itself to those who were looking for nothing more than a bronchial catarrh, "Is this influenza after all, or is it some other epidemic disease, and if some other, is it not dengue?" It is true that this misconception prevailed to a much greater extent in Europe than here, and especially was this true of the extreme East, Turkey, Greece and Austria. It may not be out of place, however, to outline the distinctive features of the two affections, not so much to enable the most of us who are present to make the diagnosis in our practice, since dengue is almost exclusively confined to hot countries, but in order that, hearing of the prevalence in Europe or Asia of an epidemic disease having a similarity to either affection, we may be able to determine its character in our own minds, and hence, the necessity for expecting its advent in this country and for forewarning the people,—or the absence of any such necessity. Certainly if our health authorities had possessed the knowledge of the character of the disease, and its rate of progression geographically, in the Autumn of 1889, which they now possess, they would have been enabled to issue—and it would have been their duty to issue—precautionary circulars, notifying the people that, at about such a time, it might be expected that from one-fourth to one-sixth of the population would be so prostrated, that they would be more or less incapacitated from attention to business, and that it would be the part of wisdom for those who found themselves attacked with the disease to give up work at once and secure medical advice. People could then have arranged their affairs in advance to meet the emergency, and many lives of those who kept at business after they ought to have been in bed, or returned to business when they ought to have stayed in bed, might have been saved.

The first point of distinction that we may make is in regard to the mode of extension of the two affections. Influenza, as we have had recent demonstration, spreads like a flood, inundating whole sections in an hour, while dengue works along gradually, establishing centres of infection here and there, enabling its course to be easily traced. In their sudden onset, intense headache, pain in the back and limbs and excessive lassitude they have much in common, but, while the fever in dengue is invariably of a high grade, in influenza it is often slight or absent altogether. The catarrhal and pneumonic complications of influenza, the dyspnoea, the feeble piping voice, are very rare in dengue, while on the other hand, the latter is characterized by violent and persistent gastric disturbances.

An erythematous eruption followed by desquamation, beginning in the face and descending, is rarely absent in dengue, and as rarely seen in influenza. Dengue very rarely terminates fatally, influenza, as we know to our cost, often does.

While, therefore, there are points of similarity between the two affections, especially in regard to their nervous phenomena, the distinctions are sufficiently marked to prevent any misconception, when large numbers of cases are under consideration.

To refer now to the history of the disease in our own country:—sporadic cases appear in our tables during the month of November. One accurate observer in Philadelphia reports a case in July. Without discrediting his diagnosis we can scarcely consider this case as due to the epidemic influence. What we are accustomed to call influenza colds, we may meet with at any time, and we are all familiar with circumscribed epidemics of influenza of a mild type. Other physicians report cases probably to be classed in the same category in September and October. About the tenth of December it began to exist epidemically on our seaboard. It was prevailing sufficiently to attract general attention in Philadelphia, by the 20th of that month. The disease began to appear as an acknowledged factor in the mortality tables of the city on the 4th day of January, when one death is recorded from the disease. An increase in the number of deaths from inflammation of the lungs, however, from thirty-three in the week previous to seventy one in the first week in January, sufficiently indicates that the epidemic had become fairly seated. It spread with a rapidity which is scarcely conceivable, and gained in intensity as the numbers of its victims increased. By the 23d of December, it was estimated that there were 2,000 cases in the city. On the 9th of January, 6,000 of the pupils of the public schools were reported as prostrated with the disease. The number of deaths increased the first week in January, from 404 in the week previous, to 492. In two weeks it reached the startling figure of 770, more than twice as great as the mortality of the corresponding week of the year 1888. The over-worked physicians were prostrated both by fatigue and by the disease itself, and many succumbed finally.

Business was now almost at a standstill. In several instances places of business or manufacture were compelled to close for want of hands. Whole families were confined to the bed at once, so that neighbors were obliged to provide them with food and nursing care. This week, ending January 18, marked the high tide of the pestilence in Philadelphia so far as mortality was concerned, the city death-rate having fallen to its norm by the end of February. In the meantime the epidemic influence had spread like wildfire, literally "on the wings of the wind" throughout the entire State. On the 27th of December the disease was rife in Lancaster, and genuine cases had appeared in Pittsburgh on the extreme western border, and Wilkesbarre on the northern border of the State.

It is probable that not a single individual entirely escaped its pernicious effects. Its manifestations were so various, affecting in one the bronchial tubes, in another the nervous system, now the brain and now the bowels—here peritonitis and there pneumonia, that it was a long time, comparatively, before physicians, even, recognized it in its protean forms. It is scarcely conceivable that a disease which spread with such astonishing rapidity, goes through the process of re-development in each person infected, and is only communicated from person to person or by infected articles. And yet this theory has been maintained by a few authorities who claim that it is always more prevalent along lines of travel, and that it did not progress more rapidly than modern means of communication would enable it to do.

Whatever theory we may adopt of its means of propagation, it was felt by the writer that an affection so fatal in its results and so widespread in its domain possessed an importance which entitled it to especial study. He therefore prepared the following circular, cyclostyle copies of which, to the number of more than seven thousand were distributed to the members of the medical profession throughout the State of Pennsylvania:

Dear Doctor: I am desirous to obtain reliable statistics in regard to the recent pandemic of influenza as observed in this State. Will you therefore, kindly furnish the information called for below, by filling up the blanks from the data in your visiting list or note book and returning the sheet to me as early as practicable?

Yours very respectfully,

(Signed) BENJAMIN LEE, M.D.,
Superintendent of Vital Statistics.

Residence—County—Date of first case—
Number of cases—Adults—Children—Pre-
dominant type—nervous—Catarrhal—Inflam-
matory—Number of deaths—Directly caused—
(Indirectly caused)—
Immediate cause of death: Bronchitis, Adults—
Children—; Pneumonia, Adults—Children—;
Phthisis, Adults—Children—; Nervous affec-
tions, Adults—Children—.

Up to the 1st of May, 4,500 of these letters had been sent out.

The following is an analysis of the results obtained at that date:

Number of physicians reporting	265
Number of cases	37,375
Adults	26,302
Children	10,973
Number of cases nervous	6,913
Number of cases catarrhal	16,434
Number of cases inflammatory	5,829
No. of deaths directly caused.	591
No. of deaths indirectly caused.	2051
Immediate cause of death, bronchitis.	8
" " " pneumonia.	117
" " " phthisis.	31
" " " nervous.	42

Supposing, which there is no reason to doubt, that the 265 physicians who replied, represent a fair average of the practitioners of the State, this would give us 1,120,000 persons as having been

sufficiently ill with the disease to demand medical aid or come beneath the observation of a medical man, and 7,879 deaths directly or indirectly caused by the epidemic influence in the State of Pennsylvania alone. We know that there were many who suffered mild attacks who never sought advice, and many more whom physicians, in their excessive haste, failed to enter on their visiting lists although they may have prescribed for them.

In fact this is exactly the return that was made in some instances:

"Treated an immense number of cases but kept no record."

Nearly one-half of the cases reported were in the city of Philadelphia. As the Philadelphia physicians reporting constituted only about one-third of the whole number, the disease must therefore have been more prevalent in large cities than in the country. To be exact, the average of cases to each physician reporting was 140; while the average to each Philadelphia physician reporting, was 193.

The disease seems to have been especially prevalent in mining towns. Two physicians in Shamokin, a place of about 12,000 inhabitants, report 950 cases between them. In Greensburg, a place of about 6,000 inhabitants, two physicians report 737 cases. In the little village of Portage, Cambria County, numbering 650 inhabitants, one physician reports 400 cases. Ill-fated Plymouth suffered seriously as did the most of the other mining towns and villages of Luzerne County. Scranton was also severely visited.

One curious fact developed by the investigation is that the disease was observed quite as early in the extreme western portion of the State as in Philadelphia on the eastern border. Indeed more observers in proportion to the population report having observed cases in November in Allegheny County than in Philadelphia County; as though a disease bearing air current had passed over the eastern border at a great altitude and dipped down in the western portion of the State.

Of the 265 physicians reporting 206 made the distinction as to the predominant type of the disease. While it is to be regretted that all did not, still this number, representing more than 29,000 cases, is ample for purposes of deduction.

Nearly 7,000 of these are recorded as belonging to the nervous type. This is very nearly 25 per cent, and does not, of course, preclude the presence of nervous symptoms in a large proportion of those set down as catarrhal or inflammatory. And this takes us back to the point from which we started, namely the marked predominance of the nervous element and the protean character of the manifestations in this singular affection. How shall we account for

the production of such varied morbid phenomena by a single morbid agent.

Some writers, among whom may be mentioned Dr. Dixon, of the University of Pennsylvania, attempt to explain it by saying that the disease lowered the vitality of the cells of the various tissues so that they were no longer able to resist the onslaughts of the microbes of the various diseases, and that any that happened to be present found an entrance and developed their peculiar affection. Others, as Dr. Baker, Secretary of the State Board of Health of Michigan, consider that the atmospheric condition affected the lining membrane of the air passages in such a way as to make it easy for the ever present germs to find an entrance into the blood; and, as in the first mentioned theory, that each produced its characteristic chain of symptoms.

One great obstacle to the acceptance of these theories is the fact, that they require the existence of a great number of microbes of which we have no knowledge.

To the writer it seems more rational to suppose that the morbid influence, whether germ, microbe or occult meteorological departure from the normal condition, spent itself directly upon the nervous system, and more particularly on the vegetative portion of that system, or to particularize, still further, upon the pneumogastric nerve and its associated ganglia with partial implication of the spinal cord. Nearly all phenomena which distinguish influenza from other similar affections can be readily accounted for by this theory; the excessive nervous prostration, so entirely out of proportion to the catarrhal disturbance, the emotional depression, causing the victim to weep incessantly without consciousness of any reason for so doing, the sense of constriction about the larynx, the strident cough, piping voice and occasional aphonia, the sudden congestions of the lungs, the pain and stiffness in the dorsal muscles, especially along the nucha, the gastric and intestinal disturbances, the intense headache, and transient manias, all can be accounted for by the supposition that the great balance wheel of organic life has become deranged—and on no other theory so simply.

The fact that all the remedies which were found most beneficial in the treatment of this affection are nervines, such as phenacetine, morphia and *nux vomica* may also be adduced as strongly confirmatory of this theory.

1532 Pine St., Philadelphia.

A VERDICT of \$100 damages has been given against a London chemist who supplied ammonia when sal volatile was asked for. The plaintiff, an actress, was said to have been prevented from following her engagements for nine days as a result of the mistake.

NOTE ON THE BATH TREATMENT OF TYPHOID FEVER.

BY SIMON BARUCH, M.D.

OF NEW YORK

PHYSICIAN TO THE MANHATTAN GENERAL HOSPITAL AND NEW YORK JUVENILE ASYLUM

In the article "Has progress been made in the Medicinal Treatment of Typhoid Fever?" Dr. T. J. Happel, after reviewing the various methods of medicinal treatment, goes out of his way to attack the Brand Treatment (which certainly is not a "medicinal" treatment).

I feel called upon to say a word in defence of the bath treatment which he dismisses so summarily. "The bathing must be begun early," says the author (p. 811) in quoting the directions I gave in a review before the Academy of Medicine, "even before a diagnosis can possibly be made. I would suggest that the longer before a diagnosis can be made, the bathing is begun, the greater the per cent. *me judice*, of cures, because the greater the number of febriculae and simple continued fever cases you are apt to have to treat."

It does not seem to have occurred to this gentleman that men like Ziemssen, Juergensen, Vogl, Brand, Tripiet, and other eminent clinical teachers are as capable of making a diagnosis of febricula from typhoid as he is, and that they do not regard a case as typhoid unless it runs its characteristic course.

Again, this author says (p. 811): "If we wait until we are fully satisfied that we have a case of typhoid fever, we will find that Brand's method will offer no advantage over former methods of treatment." This positive dictum of the author would presuppose that he has given these methods a fair trial, which I greatly doubt, on account of the horror he expresses of the Brand method. Moreover, I deny that "its advocates must admit that it is as yet *sub judice*."

In discussing this question I have been careful not to obtrude my own personal experience, although it extends over twenty-eight years in military and civil, private and hospital, village, country and city practice, North and South. The experience of one individual is valuable only as a part of the aggregate, *unless it be very large*. Such an experience we have obtained from Vogl, the chief of the garrison hospitals of Munich. As this is only confirmatory of Brand, Ziemssen, Juergensen, Struempell and others, and as he is not the originator of the method, we may in all fairness accept his statements as positively free from bias, and incontrovertible. Vogl tells us that he was led to abandon all other treatment of typhoid fever, in favor of the cold bath, by studying the records of the institutions under his charge for forty-seven years. During this period every method in vogue had been applied in 8,325

cases of typhoid fever. The various types of disease are clearly pictured in his work, giving symptoms, complications and pathological changes. From venesection to nihilism, and, later, antipyretics and baths; the gamut was run as was the fashion at different times. Since 1868 the bath treatment has been used in 559 cases; alone in one station and combined with antipyretics in another, with the following results:

	Cold Bath Treatment	Hot Bath Treatment
Mortality	6.7 per cent.	27.7 per cent.
Average hospital stay	40.3 days.	47.5
Per cent. complications	102	65.2
Average number diarrhoeas per person per day	1.4	0.7

The mortality under the old treatment ranged from 40.3 per cent. down to 7.6 per cent. These figures will, I trust, convince your readers that Dr. Vogl did not mistake febricula for typhoid fever, and as they only sustain the verdict of a large number of equally capable and honest hospital physicians, they demonstrate that the superiority of the bath treatment is not, as your author supposes, "still *sub judice*." Medical statistics are proverbially unsatisfactory, but if ever they approach exactness, these of Dr. Vogl are an instance; for here we have a military hospital, under various administrations during forty-seven years, treating exactly the same class of patients, soldiers of about the same age, previously in good health, having the same employment, the same food etc. Surely no better data for a comparative estimate of a question in medicine can be imagined. And yet the author has the temerity to tell your readers, "I enter a protest that the mortality of typhoid fever cannot be reduced to 3 per cent. by any such procedure, but that the errors in diagnosis account for the vast discrepancy."

Upon another point I must take issue with the author when he says: "Antifebrin given in such doses as the patient is found to bear, will accomplish in one hour what is effected by the Brand system in three times that length of time." If the author had ever tried a genuine Brand bath he would have discovered several errors in this proposition, the principal one being that the effect of the bath upon the temperature and pulse is obtained, not in "three hours" after the bath, but in fifteen minutes. If the author had studied recent developments in experimental therapeutics, he would also have known that Lépine demonstrated in the Paris Congress of Therapeutics in 1888 that antipyrin and antifebrin lower the vitality of the protoplasm, that they convert the hæmoglobin and attack the cell structure and destroy the red blood corpuscles. It was generally accepted that they undermine every organic function, hence they are dangerous in a disease recovery from which depends upon their integ-

¹ In the Journal of the American Medical Association, December 6, 1890.

city. Vinay also shows that they diminish the excretion of urea and nitrogen. That this is not mere theory is proved by the almost unanimous verdict against the use of antipyretics in typhoid fever, given by the American Association of Physicians in 1887, and in favor of the bath treatment by the Wiesbaden Congress of 1885.

I agree with the author upon one point, viz., the Brand bath requires a considerable outlay of trouble. But when we consider that it saves the involuntary soiling of beds, the muttering and wild delirium, the frequent diarrheas, and, above all, that it saves enormously in mortality; that it abbreviates convalescence and cheers the family and friends, the latter, even in the country, will not be averse to the additional trouble for fifteen minutes every three to six hours. The water need be changed only once in twenty-four hours, unless the patient soils it. If it cannot be executed with precision, the nearest approach must be made, just as we, who have practiced in the country, were so often called upon to do.

My friend, the late Dr. Trantham, of South Carolina, once did a craniotomy with a jack knife, and did it well. In my experience, country physicians, many of whom I have in former times met in consultation, are the readiest men, most full of resources, whom I have ever met. They will not fail to invent some means by which they will nearly substitute the Brand method. If they can accomplish it, those living in towns and cities will not fail to do so. In *Gaillard's Medical Journal* for January, 1891, such methods are fully given, as I have found useful in the past. The principles of the bath should always be borne in mind. *A temperature of the water not below 65° nor above 70°, duration ten to fifteen minutes, constant friction of the surface.*

There are many points in the paper of Dr. Happel which tempt me into criticism, but I have referred only to the most salient point of his argument, which seems to be a denial of the mortality reducing value of the bath-treatment upon the ground that "errors of diagnosis account for the discrepancy." The untenability of the argument (?) is proven by Vogl's plain statement of the duration and complication of his cases, and the results.

KOCH TREATMENT OF TUBERCULOSIS.

BY SOLOMON SOLIS-COHEN, M.D.,

OF PHILADELPHIA.

In the Polyclinic evening lecture course, February 17, Professor Solomon Solis-Cohen reviewed the published records of cases treated by the method of Koch. He stated his continued disbelief in the etiological rôle ascribed by the ma-

ajority of cotemporary writers to Koch's bacillus. The work of Dr. Heneage Gibbs was highly commended, and close attention asked for the facts brought out. The close association of Koch's bacillus with certain forms of the diseases called tuberculous, and its possible determining influence in the destructive outcome of the lesions, were admitted by the lecturer. But the actual disease in the preponderance of cases he found in that condition of system or cells which permits the bacillus to find pabulum in the tissues. Given this condition, the reaction between the tissues and the bacillus gives rise to some product which destroys tissue. If we produce this substance outside the body and inject it, we destroy tissue more quickly. This is what Koch's method does. The poison or poisons—ferment, toxine or whatever it or they may be—generated by the mutual reaction of the bacillus and the tissue, being dissolved in glycerine is called "Koch's remedy," and is injected. In subjects of tuberculous disease it causes the process to become more rapid. The affected tissues dying, the microbes are deprived of food and starve to death. If the lesions are external the dead tissues are cast off and temporary recovery takes place. But the condition of the remaining tissues permitting them to succumb is not cured unless this is accomplished by other means, and relapse, that is to say reinfection, may occur at any time.

When the affected tissues are not external, even if only slight lesions exist, the inflammation, ulceration and hæmorrhages produced may be fatal, as in the cases reported by Chiari, Virchow, Fraenkel and others. In other words, a case that might last months, or even years, completes its destructive course in a few days or weeks. Even in external cases in highly susceptible patients, rapid spread of the disease may result, as in Fraenkel's case of tuberculosis of the tongue. Cases have been reported also in which after the injection bacilli were found in the blood. In the meninges or the brain the local reaction is almost sure to have fatal results by compromising important structures. In the larynx occlusion from local reaction may necessitate prompt tracheotomy. In cases with extensive pulmonary cavities further destruction means immediate death. It is only fair to Koch to recall that the counter indications in cerebral, laryngeal and extensive pulmonary tuberculosis, were pointed out by him.

It is claimed that reaction occurs only in subjects already tuberculous.

Dr. Cohen doubts this. He points out that human beings may clinically be divided into three groups: 1. Those highly susceptible to tuberculosis. 2. Those moderately susceptible. 3. Those insusceptible. The first and second groups are subject to many subdivisions which need not be considered in detail in this connection, and individuals of the third group might under pecu-

liarily depressing environment acquire temporary susceptibility. If Koch's virus be injected in moderate quantity in a nonsusceptible person, no harm might result. If injected in a highly susceptible person, even if he had not already acquired the disease, the injection would probably give it to him. The reaction proved not the previous presence of the disease, but the susceptibility of the patient, and possibly the acquirement of disease from the injection. Its diagnostic use is like setting fire to a house in order to find out if the house is fireproof. It might be fireproof—in which case no harm would be done—but then again, it might not. One further danger, the speaker said, had been illustrated in a case not yet reported, of which he had personal knowledge. The patient had both laryngeal and pulmonary disease, and most probably would have perished in the natural course of events, after a somewhat more prolonged illness. The point to be made, however, was independent of the actual condition of this patient. Death occurred after profuse hæmorrhage. Old and unsuspected cicatrices had broken down in the lung, and while recent lesions had been apparently favorably influenced, death had occurred from extensive destruction of the salutary work formerly accomplished by nature, unaided. This seemed to indicate that in subjects of a certain degree of susceptibility, tubercular formation might go on to fibroid change, the bacillus being unable to bring about necrosis; but by injection of the necrosis-poison the fibroid tissues, being still weaker than normal, might succumb, and a patient whom nature was curing, be slain by art.

Moderate susceptibility was proved by the existence of lupus for many years, or of certain joint lesions, or glandular lesions for many years, without fatal involvement of important organs. The fire was there but it only smouldered. The house then was partially fireproof. In these cases it might be very good practice, where it was impossible to thoroughly cut away the smouldering portions, and where they were favorably situated for this purpose, to cause them to burn out quickly and thus limit danger of further spread. Hence Dr. Cohen believed the Koch treatment justifiable in chronic lupus and chronic joint tuberculosis of long standing, without serious visceral involvement. The chronicity of the disease proved that the patient was only moderately susceptible. It might, and did, in joint cases, at least, require surgical aid to remove the débris.

In lupus or joint lesions of short standing, however, other measures should be used at first, and only after these had failed and time had proved comparative insusceptibility of viscera should the Koch remedy be used. A case recently reported of death in a girl of 17, with lupus, after one injection of two milligrams, was cited in support of this position.

Dr. Cohen said in conclusion that in incipient phthisis the remedy was not needed. Food and air, with exercise and rest appropriately alternated—in other words *nutrition*, with the aid of creosote, iodoform and a few other drugs at suitable times limited the spread of the disease and brought about recovery in all cases where recovery was possible. Those highly susceptible did not recover, but had their lives greatly prolonged. Injection of iodine or other medicaments, as recommended by Dr. Shurly, might prove to be of assistance. The speaker was now making some observations with Shurly's method. In acute miliary tuberculosis, or in chronic phthisis with large cavities, Koch himself had said that his remedy was counter-indicated.

Dr. Cohen therefore limited its use to appropriate cases of lupus and joint-disease, or other external lesions whose course and duration proved the patient to be only moderately susceptible. It had been said that the death-rate was only 1 per cent., 85 cases in 8,500, but what physician would dare to prescribe opium, arsenic, or even quinine indiscriminately, if it killed one patient out of every hundred? Furthermore, if the proportion of deaths to injections in phthisis alone were considered, it would be found to reach a far more alarming percentage. For the present, at least, he did not hesitate to declare the use of Koch's remedy in phthisis a practice full of danger.

THE CLINIC.

A CLINICAL LECTURE ON INSANITY.

Delivered at the Insane Hospital, Danville, Ill., to the Students of the Woman's Medical College of Chicago.

BY DANIEL R. BROWER, M.D.,

PROFESSOR OF DISEASES OF THE NERVOUS SYSTEM, DIDACTIC AND CLINICAL, IN THE WOMAN'S MEDICAL COLLEGE; PROFESSOR OF MENTAL DISEASES IN RUSH MEDICAL COLLEGE; PROFESSOR OF DISEASES OF THE NERVOUS SYSTEM IN POST-GRADUATE SCHOOL, CHICAGO, ILL.

[Reported by ELIZABETH H. TROUT, M.D., Assistant to the Chair of Nervous Diseases Woman's Medical College Chicago.]

Case 1. Melancholia.—The delusions of melancholia, as we have told you, are of a very depressing character. This woman, you will see at a glance, is perfectly miserable. Her delusions are of the religious type, as they frequently are. All varieties of this disease have the fundamental character of melancholia, viz.: the depressed emotional state, as their essential feature.

The temperature in this case is normal, which is unusual. In acute melancholia the temperature is generally below normal.

Case 2.—Here is a case showing the characteristic position that these patients assume in the early stage. The head is bowed upon the chest, the eyes drooped, the expression thoughtful. She is apparently in deep meditation, she evidently

has some weighty matters on her mind. She never speaks. Her temperature is depressed, as is usual in these cases. After the melancholia has existed for some time, if the patient becomes excited the temperature will not be subnormal. An interesting feature of this case is, that it is the outgrowth of lactation. We have connected with the life of woman the insanity of pregnancy, of the puerperal state, and of lactation. The insanity of lactation usually manifests itself as is illustrated here. The delusions are of a depressing character. The insanity of pregnancy is usually of this type also, while that arising out of the puerperal period is generally maniacal.

The depressing influences surrounding the pregnant state, and the physical exhaustion resulting from lactation, have doubtless a great deal to do with these cases assuming this type of insanity. Women in these conditions suffer from insomnia, impaired appetite, disturbances of digestion, etc. There are many important etiological factors. The prognosis is less favorable than that of mania.

Cases 3 and 4. Mania.—Here are two cases of puerperal insanity, usually so called if it occurs during the first six weeks of parturition. It is a form of mania. Note the difference in expression and attitude from the cases we showed you a moment ago. The head here is held up; see the constant play of the facial muscles and the activity of the entire body. The delusions of these cases are of the happier type: expansive delusions. The circulation is quickened, the pulse is 120. Note the contrast to the absolute rest and quiet of the cases of melancholia just shown you. The insanity of the puerperal period is the most fortunate form of insanity to encounter. The proportion of recoveries is about 80 per cent. They are to be treated by such remedies as will control the violence of their activities, and depress their nerve centres, and by nutrients and eliminants. These patients must have a large amount of food and rest. Eight or nine hours of the twenty-four should be spent in sleep, and to produce this, some form of narcotic should be given: chloral or sulfonal. The latter acts well in many cases. You must give some sleep-producing agent that will accomplish the result without too much depression of the circulation. Sulfonal is not commonly a cardiac depressant, and does not usually interfere with the nutritive processes. The deodorized tincture of opium is often beneficial. Preparations of morphia are sometimes very valuable in these cases. Some of the opiates will produce sleep better than such depressants as bromides or chloral. Tonics are to be administered judiciously: preparations of malt, iron, strychnia, quinine and the hypophosphites. The food should be of a very nutritious character and easily digested—milk, eggs, beef extract, etc. You must bear in mind the fact that the exciting cause may be in the uterus or its appendages; as subinvolution or partial in-

version. In fact, you should examine carefully every organ in the body and correct, if possible, any departure from the physiological standard.

In melancholia we find a sluggishness of the alimentary tract. These patients need laxatives much more than do the manias. The aloetic purgatives are the most useful here. The food also in melancholia should be easily assimilable, and if the patients refuse to eat, as they frequently do, no time should be lost in resorting to artificial feeding. The nutritive processes are very much disturbed, and to allow these patients to go without food would be very injurious. The prompt use of forced feeding, in some cases, hastens the return of the physiological habit. The medicine can be administered at the same time. The proper treatment of lithæmia and allied conditions, if present, should be prompt, and may be remedial. Patients whose temperature is subnormal should be kept in warmer apartments than those of the sthenic type. These patients need cardiac and general stimulants also.

Case 5.—Here is a case of acute mania of three or four months' duration. The facial expression is one of pleasure. The activity of the muscles of the face and body is very great. The circulation is quickened. The delusions are of the expansive type, as with the puerperal cases.

Case 6.—This is also a case of mania. She has been in this condition a long time, she is a kleptomaniac. The tongue is coated, digestion disordered, the pulse quickened, but not to the same extent as in the case just shown you. You will also notice that the activity of the muscles is not so great.

Case 7. Chronic Melancholia.—I will call your attention in this case, to the peculiar appearance of the finger-nails. Fothergill calls it the "gouty finger-nail." It is well shown here; it consists of rough, somewhat irregular, whitish ridges, running longitudinally. You will also notice in this case the discoloration of the hands and feet, due to some error of the circulation. The hyperæmia is probably due to degeneration of the blood-vessels. These defects accompanying insanity are very interesting. They serve to teach us an important fact, viz.: that insanity is a disease of the whole organism; no person can be insane without having more or less disturbance of the whole organization. "A person who is insane is insane to his finger ends." Such is the intimate connection between the brain and the periphery, that it is impossible to have an amount of disturbance of the brain sufficient to produce insanity without great physical or constitutional disturbance, and more or less want of nutrition all over the body. To find a person of insane mind with a perfectly healthy organism would be an impossibility. The "Fothergill finger-nails" show disturbed nutrition and a defective circulation. The temperature is subnormal, and her de-

lusions are of the most depressing character. The peculiarity of the mental disturbance in this case is that the woman does not talk at all. It is a case of chronic melancholia of many years' standing. There is considerable malformation of the head here, excess of development of the left side compared with the right. These defects are very common, especially in monomania. Take a picture of first one side of the head and then the other, and you have really pictures of two individuals.

Cases 8 and 9.—Here are two excellent cases of chronic melancholia. You see that they assume the characteristic attitude: the head bowed upon the chest, the hands resting upon the knees. They also show the disordered circulation, the peculiar disturbance so common in these cases; a congestion of the capillary system. I presume that for a pathological basis in many of these cases there is a similar condition of malnutrition of the brain, such as you see so well marked in the hands of these men.

Melancholia remains as such for many years. All cases both of mania and melancholia are tending either towards recovery or towards that other form of insanity to which we called your attention a few days ago, dementia. Both these cases are nearing the latter type. This condition is recognized by the loss of memory, the untidy habits, etc. These patients become more and more slovenly until finally they cease to pay any attention to their personal appearance, and become exceedingly negligent and dirty in their habits. During the active stage they are simply depressed, they have the same mental capacity that they ever had, only they are under the influence of their delusions. What is simply functional in the beginning becomes organic. The brain cells are slowly destroyed, they atrophy, and these people literally lose their minds and become demented. This we call secondary or terminal dementia. These cases are all more or less hopeful until the memory begins to fail; when this occurs and dementia is established there is no possibility of recovery.

Case 10. Monomania.—Here is a case with a fixed and limited delusion. This woman is under the impression that she is engaged and is to be married. She prepared her trousseau. There is no rational basis for her delusion. The man she expected to marry was ignorant of the whole affair. Along with this form of insanity that takes the neurotic character, there are certain physical defects. These cases have been recently termed "paranoias." They come into the world physically defective, but their mental derangement is not usually manifest until puberty. The mind is enfeebled, but they are not imbeciles; they may possess considerable influence. Their delusions are systematized and are often of the exalted type, in the way of pride or grandeur. In this case

there is no physical defect apparent, and outside of this one delusion, she seems to be all right. These cases form a large percentage of insanities. It is an embarrassing class, as it is difficult to apply the tests of insane delusions. You will often be perplexed as to these cases of monomania. Mahomet was one, Peter the Hermit, who led the Crusades, was probably another, Guiteau another. The man who shot at Edwin Booth was probably one also. His delusion was that Booth was his father and was neglecting him; acting upon this, his whole life was shaped at redress. He followed him about from place to place, annoying him greatly, and finally shot at him in McVicker's Theatre, in this city. Outside of this particular line of mental derangement, he seemed to be perfectly rational. He imagined he possessed great dramatic ability, and endeavored to secure an engagement with one theatre company or another. These people frequently have the power of hiding their delusions; you may study them for weeks without finding them out.

Cases 11, 12 and 13. Epileptic Insanity.—Here are three epileptic cases. Epilepsy is a disease of the brain. All epileptics are drifting towards insanity. It is a possibility with any of them, although it occurs much more frequently with the petit mal type than it does with that of grand mal. Petit mal attacks are just as serious, if not more so, than grand mal, on account of the frequency of their occurrence. A patient will have several of these attacks of petit mal in one day, thus keeping the brain in a state of commotion. Insanity that grows out of epilepsy is most perplexing. All these insane epileptics have defective inhibition. They are impulsive, liable to sudden outbursts. In the interval between their attacks they are often the most useful people in the hospital—kind and industrious. During their paroxysms they are often very dangerous. These epileptic manifestations are usually preceded and followed by a state of excitement. Irritability and epilepsy go hand in hand; almost all these cases are irritable above the average person, they are also vacillating. They are the most unsatisfactory patients the physician has to deal with. They will be under your treatment for awhile, then get discouraged, and travel from one doctor to another. They lack fixedness of purpose, are irritable always, and may be exceedingly violent during their paroxysms. This case shows well the asymmetry of the face, and also a deformity of the chest.

Case 14.—Here is an interesting case of epileptiform insanity showing discoloration of the face—"argermism." This is caused by a persistent use of the nitrate of silver. He took the drug for five or six years. In using this drug it should never be administered for more than three months at a time, and the amount given should not exceed 90 grs., 1 gr. per diem. This will produce

whatever benefit is to be derived from the drug. After a long interval you can repeat the treatment. In this case no benefit was derived from its use, nor is there any to be expected except in those cases that are stomacheic in their origin.

Case 15. Hemiplegia.—This case you see has lost the power of the arm. There is some contraction of the fingers and also of the foot. There is also exaggerated patellar tendon reflex, and aphasia. She understands perfectly well what she wants to say, but she cannot say it. It is a case of amnesic aphasia; the power of speech is lost because of the loss of memory of words. Articulation is not lost. The doctor tells us that there was a blocking of the internal saphenous vein. The case may be one of embolism, but because she has lost the power of expressing her ideas she was supposed to be insane. There is no other evidence of insanity. In right-sided hemiplegia there is always some aphasia, and when the lesion is pronounced it cuts off the speech centre from the parts below. Such a condition as this might serve to impress some people with the idea of insanity. The case is of interest to us only as one of mistaken diagnosis. She is not insane, but it serves to show us the necessity of making a careful examination.

I will now call your attention to another type of insanity: *Paretic Dementia—General Paralysis of the Insane*. This disease usually occurs in the prime of life, and is much more frequent among males than females. In females the disease runs a slower and more even course; the delusions are not, as a rule, so expansive, nor the remissions so abrupt as in the male. We have two varieties: the ascending type, beginning in the spinal cord, and the descending type, beginning in the cerebrum. The average duration of the disease is about three years, although it may terminate much sooner or extend over a period of many years. All cases of paretic dementia have many symptoms in common: the peculiar thickness of speech, the inequality of the pupils and their immobility to light, the clumsy walk, and their unsystematized delusions, usually of the expansive type, of wealth or grandeur.

Case 16. Female.—This woman, you see, has the depressive form of delusion. She imagines that she has been greatly wronged. It is very uncommon to find the delusions as depressive as they are in this case, even among women. You will notice here the peculiar defect in speech. Later along this defect becomes aggravated by the increasing amnesia of the patient, causing the frequent use of the wrong consonant. A characteristic feature of the later stages is the unnecessary movements of the lips and tongue, associated with those of other muscles, upon efforts at speaking; the nostrils dilate and contract alternately, the corrugation of the occipito-frontalis muscle increases, and after all these spasmodic

and exaggerated movements, the word is thrown out as though it had to force its way through some impediment. This case shows some inequality of the pupils, and has exaggerated patellar tendon reflexes, showing that the spinal cord, as well as the brain, is involved in the degeneracy.

Case 17. Male.—Here is another case of paretic dementia. This man says there is nothing the matter with him. He feels first-rate. He tells us he is worth \$30,000; he is happy, satisfied with himself and his surroundings. Note the similarity in speech in this case and the preceding one. We have here, also, inequality of the pupils—contracted, in this case; they are also immobile. The delusions of this man are of the character usual in this disease: the expansive, happy type. These people simply assert their wealth, or grandeur, or whatever it may be; they do not reason about it; their delusions are all unsystematized. Compare the appearance of this man to that of the woman. The mental deterioration is just as serious in one case as the other. The man, you see, has a satisfied, happy look, while the woman is perfectly miserable.

Case 18. Male.—Here is another typical case. He says he is not so well as he expects to be, but he imagines he can jump, box and spar. He also thinks he is a graduate of Yale, and valedictorian of the class. You see he is self-satisfied and happy. Notice here the same disturbance of speech, the same pupillary phenomena, and the same exalted character of the delusions.

Case 19. Male.—This man imagines he owns all the real estate in the world, all the horses, and every stick of wood. He has the same air of satisfaction and content, and all the symptoms enumerated in the two preceding cases.

Case 20. Male.—This man tells us he is wealthy; he imagines he can sing and dance. You see, he is happy and contented. He has the unequally dilated pupils, the clumsy walk, and the same defective speech.

Case 21. Male.—Here is another wealthy (?) paretic. He owns the State of California. He has the same characteristic symptoms shown you in these other cases. The tremor of the tongue is present, in a greater or less degree, in most of these cases.

Case 22. Male.—This is a recent case.

(To patient): "How is your health?"

Patient: "Perfect, doctor—I'm first-rate."

Prof. B.: "How long have you been here?"

Patient: "Three or four weeks."

Prof. B.: "Why did you come here?"

Patient: "I ran for Senator at the election. I had no money. The boys came around for some 'stuff.' I had none, and they attacked the house and broke the windows. Some one came to protect me, and took me to the Town Hall; next day my house was set afire and burned. That disturbed me, powerful. Some of my children came down to tell me about it, and were run over by a train."

Prof. B.: "How much of a majority were you elected by?"

Patient: "I don't know, exactly. It was pretty fair."

Prof. B. (to class): "This is all a delusion."

Patient: "Oh no, it is not."

Prof. B.: "Well, we may need your assistance in the Legislature."

Patient: "You shall have it, with pleasure."

During the early stage of this disease, depressive delusions may occur, as in this case. The defect in speech is noticeable in this case, and there is some inequality of the pupils.

The prognosis of this disease, while not absolutely hopeless, is bad. Treatment is of service only in the early stage. If the condition is recognized during the prodromal period, you may possibly be of some service to them. In the cerebral form, this stage presents as its most notable sign, a change of character. The heretofore careful business man becomes negligent, the kind husband and father, indifferent or irritable. The memory is early affected and, at first, relates to trifles. As this period progresses, more serious omissions and errors occur. He becomes irregular in his habits, forgets his appointments, and along with these symptoms the morals begin to totter. The patient forgets his moral obligations to himself and to his family. His walk becomes less steady and regular. The legs are thrown wider apart in order to widen the base of support. During this stage the patient may be more or less depressed. At the close of this period the depression, if it existed, disappears, and delusions of grandeur take its place, often coupled with extravagant expenditures. There is also an increase of all the physical signs. This excited condition may last a few hours, days or weeks, when a remission occurs and the patient apparently recovers. In the majority of cases, tremor of the hands, inequality of the pupils and a slight speech defect are more or less prominent during the remissions, which may last from three or four months, to years. With every exacerbation, the physical signs increase, and the mental deterioration becomes more manifest. When the disease is recognized, the patient should at once be put to rest, physically and mentally. Mild alteratives combined with tonics may be of some service. The blood supply to the brain should be regulated, by such remedies as bromides, ergot, etc. Narcotics of a non-depressing character should be used if necessary, and the diet should be carefully attended to. Nutritious and easily digested food should be freely administered. Massage and the constant galvanic current are also of great value.

SMALL POX.—Authentic reports indicate quite a widespread existence of this disease in Texas—that is, that it has appeared at a considerable number of points throughout the State. Two cases are also reported to have been found in New York City.

MEDICAL PROGRESS.

Therapeutics and Pharmacology.

INHALATIONS OF PEROXIDE OF HYDROGEN.—GABRILOWICZ (*Nouveau Remède*, 1891), has tried the inhalation of peroxide of hydrogen in a large number of cases of affections of the larynx and trachea. He begins ordinarily with a one per cent. solution which is gradually increased in strength; in tuberculosis he recommends a beginning strength of five per cent. He has employed the remedy in a large number of conditions affecting the respiratory organs, acute and chronic laryngitis, trachitis and bronchitis.

THE TREATMENT OF ADDISON'S DISEASE, WITH KOCH'S REMEDY.—DR. HERMANN LEBHARTZ (*Sonderheft der Therap. Monatshefte*, January, 1891), contributes an exceedingly interesting case of this disease that was apparently cured.

The writer thinks that the most frequent change in the adrenals in Addison's disease consists of a caseous tubercular degeneration. In the 152 cases collected by Greenhow changes were confined to the supra-renals in 101, the bulk of these cases presented the typical picture of tubercular caseous degeneration. It is apparent that in any case of morbus Addisonii a localized tubercular process may be present in the adrenals, and therefore in the writer's judgment the use of Koch's lymph in these cases is at least justifiable.

The patient, 23 years of age, came from a healthy family of eight children. On December 24, was taken ill, with marked debility, loss of appetite, headache and fever (?), was confined to the bed until the 16th of January. One of the most prominent symptoms was frequent vomiting; diarrhea was occasionally present, alternating with constipation. From the middle of January until the beginning of May the patient was comparatively well though he complained of weakness and had occasional vomiting. A Carlsbad cure was ordered, but only increased the weakness of the patient and the frequent vomiting; at this time he was in bed more or less, had daily vomiting with alarming and frequent attacks of sudden weakness. The writer saw the patient first on the 22d of October last, when he was emaciated and greatly reduced in strength. The most noticeable appearance at this time was the intense bronzing of the skin especially marked over the shoulders, along the dorsal spines and on the trochanters; in marked contrast to the dirty yellow color of the face was the bright glistening white of the sclera, of the eye-ball. Punctiform and linear grey and bluish-black pigmentation was found on the lips, inner side of the cheeks and on the tongue. The lungs and heart were normal, the pulse small, and often

uneven: with some tenderness in the epigastric region constituted the clinical picture; no other abnormalities, such as glandular enlargements, etc., could be made out. At first a strict dietetic cure was employed, under which the patient improved in weight and the vomiting ceased. On November 16, the first injection was given, which was followed by a typical reaction. On November 20, a second injection was given, followed by reaction eighteen hours later. On November 24, an injection of two milligrams was used that was followed by marked reaction eight hours later. The fifth injection, of three milligrams produced the most marked reaction, the temperature reaching 40°C ., and such a degree of prostration as to cause much anxiety, but as the author remarks "it was the only possible method of saving the patient" so he continued the treatment. On December 5, the sixth injection of 3.5 milligrams was given, the temperature rose to 39.1°C ., but the appetite and sleep were not disturbed, while vomiting did not occur as it had previously with some of the larger doses. The seventh injection was given on December 9, four milligrams were used, but it did not cause disturbance of the general condition, and only the slightest rise in temperature from 38° to 38.1°C . December 11, 15 and 20 injections were employed consisting of 5, 8 and 11.5 milligrams respectively. These did not cause the slightest local or general reaction. From day to day the general condition improved, within the last fourteen days an increase in weight of five pounds. The appetite is good, no vomiting, voice strong, in short he presents the appearance of one convalescent from an acute infectious disease. The pigmentation remained unchanged.

The author closes with a brief *résumé* of his conclusions, which are that this method is of great diagnostic value, especially in obscure conditions such as these. He is of course, doubtful of the permanency of the cure, and insists that from time to time the lymph should be injected in large doses. He especially calls attention to the fact that the pulse of this patient did not rise with the temperature as it usually does. This he attributes to a direct inhibitory action upon the vagus, through the local action in the adrenals.

KOCH'S TREATMENT.—DR. ALESSANDRO BORGHIERINI gives an account (*Lo Sperimentale*, January 15, 1891), of the results of Koch's treatment in fourteen cases of tuberculosis of the internal organs and two cases of lupus in the Medical Clinic at Padua. Of the former, five were affected with pulmonary phthisis, seven with both pulmonary and laryngeal tubercle, while two suffered from tuberculous disease of the intestines and bones as well as of the lungs and larynx. In all the cases, careful observations

were made of the patient's general condition before, during and after the treatment. Every day the sputum, the urine, and the blood were carefully examined. The injections were, as a rule, made every second day, the initial dose being from 0.001 to 0.002g., and the amount being gradually increased by 1 or 2 milligrams at a time. The largest dose given was 0.009g. The reaction had the same general characters which are now familiar, but in two cases in which pyrexia had not previously been present, the fever, which was of intermittent type, still persisted at the date of the report (eight days after the last injection). In two cases the urine showed traces of albumen, which soon disappeared. In the larynx the local process became more acute after the first injections, this effect gradually diminishing till it ceased altogether; the local condition was very considerably modified, while the subjective symptoms were greatly relieved, and in some cases entirely removed. In the lung, the reaction consisted in a series of symptoms at the seat of the primary focus of disease, recalling pneumonic hepatization. The resolution of the hepatized tissue was sometimes speedy, sometimes slow. When it took place rapidly, resonance, which was before diminished, became exaggerated, but there always remained certain local signs, such as râles, harsh breathing, prolonged expiration. In only one case did the physical signs entirely disappear. With the modification in the physical signs, the symptoms were correspondingly mitigated; the cough became easier, the expectoration scantier, and the appetite keener. In some cases it was noticed that the local reaction in the lung was accompanied by vaso motor disturbance in the cheek of the same side. In nearly all cases diminution of the hæmoglobin in the blood was noted in the early part of the treatment, but this loss was speedily made good, and in three cases there was after a time increase of hæmoglobin. The injections caused slight hæmoptysis in patients who had previously had attacks of bleeding from the lung. As a rule, the bacilli did not diminish in number, but changes in form were sometimes observed. Borghierini sums up his results as follows: In four cases in which the disease was very mild there was "some slight favorable change in the physical conditions of the lung and in the general condition." Other factors, such as careful hygiene, good nourishment, etc., may, however, have contributed to this. In the other cases the morbid process was not modified in any way by the treatment. With regard to the lupus cases, in one (a girl, aged 8), after treatment for about a month, the local condition was somewhat improved, but the nodules could still be seen as numerous as they were before the injections were begun, only a little paler. In the other (a woman in whom the disease was of fifteen years'

standing), the injections did some good, but the reactions were so severe that the treatment could not be carried out to the extent necessary to produce any marked effect. In Borgherini's hands, so far, the injections have not been attended with any untoward result.—*British Med. Journal*.

KOCIR'S REMEDY AND ITS RESULTS.—This theme still occupies the attention of several foreign societies, notably the Berliner Medicinische Gesellschaft (*International Klinische Rundschau*, February 8, 1891). Prof. Virchow (meeting of January 23, 1891) claimed that there was but little to add to his report of the last session describing the action of the remedy upon the internal organs. He presented additional specimens, from two patients who had died in the course of the treatment, that showed fresh tubercle in different organs, in so far confirming his earlier expressed opinions.

Dr. Lassar presented a young girl that, following a tubercular inflammation of the hip, developed a large ulcer on the thigh. After a few injections with a small dose, the sore cleared up, and healed, its place being marked by a smooth cicatrix.

Flatau reported a case of laryngeal tuberculosis that at first improved, but later developed additional tubercles upon the vocal cords.

Fürbringer, out of one hundred patients, reports forty-six who have been more than two months under treatment, of these three no longer present the characteristic symptoms, fifteen have been distinctly improved, nine unimproved, and five have become worse, and seven have died. Fürbringer is of the opinion that in florid phthisis, or those presenting marked hectic, or great weakness, should not be treated.

Prof. Pribram (*Verbind deutscher Aerzte in Prag*) reports that sixty cases have been under treatment during the past two months. Of these three, he thinks, may be considered as cured. He also notes several unfavorable results: in one case dangerous hæmoptysis, and in another a rapid extension of the tubercular process that was fatal in eighteen days.

Medicine.

GUAIAICUM AND BILIOUSNESS.—DR. W. MURRELL, of London, revives the interest of old practitioners in guaiac, and invites the younger ones to make trial of the almost discarded favorite. In the *Press and Circular* he points out how, in the thirst after novelties in therapeutics, there is a danger that some of our good old-fashioned drugs may get the go-by. This is partly the fault of the text books on materia medica, for the reason that they mistakenly described the properties of the old drugs in some instances. For example, many books speak of guaiac as diaphoretic and diuretic, while Schmiedelberg, of Strasbourg,

groups it among the drugs and preparations used for all sorts of purposes, but now mostly "antiquated or obsolete." Phillips, however, in his well known work on the "Vegetable Kingdom," recognizes that the drug has a decided purgative action. Dr. Murrell had his attention drawn to the subject a few years ago by casually prescribing for a man suffering from rheumatism some lozenges of guaiac made up with the ordinary paste of black currants. The patient continued to take the lozenges long after the pains had ceased, and in explanation said that they did him good by acting on the liver and bowels. One or two lozenges taken in the morning before breakfast acted as a prompt and convenient laxative. Following up this clue, other patients suffering from constipation and that train of symptoms that are summed up under "biliousness," were treated by the same drug, and a result equally satisfactory followed in many cases. For hospital purposes, the author had a confection prepared containing 10 grs. of guaiac resin to a drachm of honey, and this became a popular purgative in the hospital, besides being used with other remedies in rheumatism, sciatica, tonsillitis and dysmenorrhœa. The dose was increased in some cases to 1 and even 2 drachms thrice daily. Taken in this manner, the purgative and "antibilious" effects are very pronounced; in one case the patient had fifty evacuations in the week. In one case an eruption was produced, covering the arms and legs, not unlike the rash of copaiba. That this kind of resultant rash is most uncommon may be gathered from the fact that Dr. Tilbury Fox did not remember to have seen more than one case like it previously. Intense itching accompanied it, and it ceased soon after the drug was discontinued. The guaiac sometimes gave rise to a sensation of burning in the throat; to obviate this Dr. Murrell frequently made use of a half-ounce of malt extract as a vehicle for each 10 gr. dose of the drug. This worked well, and may be regarded as a kind of *renaissance* of the old-time Chelsea Pensioner, which was compounded of guaiacum, rhubarb, ginger, sulphur, and some other less active ingredients, but they both have an attractiveness to those veteran cases of the hospital and dispensary that complain of torpid liver and bilious attacks. The author believes that the drug will prove itself a very satisfactory laxative or purgative, according to the dose employed. It is possible, also, that if the drug were triturated with cream of tartar, with sugar of milk, or other inert substance, its activity may be enhanced and the size of the dose reduced.

DISINFECTION OF TUBERCULOUS SPUTUM.—In the *Centralblatt für Bakteriologie*, Nos. 1 and 2, 1891, DR. MARTIN KIRCHNER points out that the general consensus of opinion has come to regard the sputum of tuberculous patients as the ordi-

nary means by which tuberculous disease spreads from one individual to another. In many of the large military establishments in Germany it has been shown that tuberculous disease has been very widespread amongst the nurses and attendants upon the sick, and stringent rules are already in force in many such places to prevent the indiscriminate disposal of sputum. Tubercle bacilli are more resistant than some other microorganisms to the action of some antiseptic fluids, but are very easily destroyed by others. Four per cent. carbolic acid, with the addition of 2 per cent. of hydrochloric acid; 2 per cent. and 5 per cent. of sulpho carbolic acid, or 10 per cent. of creolin, will suffice to render tubercle bacilli innocuous in a very short time. Caustic soda and potash, on the other hand, and 5 per cent. of permanganate of potash, have no effect, nor is a solution of 1 in 1,000 of corrosive sublimate sufficient, owing to the highly albuminous character of the sputum in which the bacilli are contained. It has now been proved that tuberculous sputum may retain its infective properties for ten months even after decomposition or drying up. It must, therefore, be equally active as it lies in the various receptacles which have been devised for its reception. The methods by which these vessels are cleaned becomes a matter of considerable importance. Boiling water is used in some places, but it is open to the chance of the water becoming cool before it can be used, and does not do away with the necessity for the wiping of the adherent sputum from the sides of the vessel by the hands of the attendant. A temperature of 70° C. has been shown to be insufficient to render tuberculous sputum innocuous, and the author of the paper believes that absolute disinfection is to be obtained only by means of steam. This plan was advocated by Grancher and De Gennes in 1888, but the apparatus devised for the purpose was cumbersome and costly. Now that there is a general disposition to treat tuberculous cases on much the same lines as leprosy cases, by collecting them together, it should be an absolute law that all the sputum proceeding from such cases should be rendered harmless before it is disposed of in the common drains. With this object, Dr. Kirchner has caused a form of disinfecting kettle to be constructed, consisting of a round metal box about 10 inches high and 16 inches in diameter, its floor forming a shallow tank to hold the water to be vaporized, the whole being covered with a lid perforated at one point for the passage of a thermometer. In this box are placed two or more trays, perforated to permit of the free circulation of steam, and so arranged as to carry five spitting-cups of the special pattern which he uses. These cups are placed for half an hour within this apparatus, heat being maintained so that the temperature of the steam never falls below 100° C. A strong protest is made against the use of the

ordinary spittoon, whether filled with sawdust or some antiseptic fluid. The spittoon is of necessity too far removed from the patient's mouth to ensure that all the expectorated matters are collected by it. The state of the floor round and about any spittoon in a public place is appealed to as sufficient evidence of the truth of this statement. Small cups made of glass, with wide lips and easily cleaned, should be used in preference to the spittoon, but must be placed within reach of the patient's hand, and be clearly labelled. These cups must be placed in the disinfecting box for half an hour before they are emptied, and their contents may then with safety be treated by simple washing.—*British Medical Journal*.

Surgery.

STOMACH RESECTION.—February 6 Dr. PORGES presented to the Aertztliches Veremisleben, in Wien, a middle aged man in whom Prof. Maydl, the previous August, had resected at least half of the stomach. The carcinomatous mass was adherent to the pancreas, necessitating a removal of a portion of that gland, as well as a part of the greater and lesser omentum. The patient apparently fully recovered and up to the present has shown no signs of a return of the disease. In discussing the case Kahler contended that the entire removal of the stomach was practicable, as the small intestine was amply sufficient to provide nourishment.

Bacteriology.

ACTION OF KOCH'S LYMPH ON HEALTHY ANIMALS.—M. JACCOUD has recently communicated to the Académie de Médecine, Séance du 10 Février, 1891 (*Le Bulletin Médical*) the history of a guinea pig that was inoculated with Koch's lymph, and subsequently with the tubercle bacillus. The pig, exceptionally robust and strong, weighing 580 grams, received two series of daily injections separated by an interval of eight days, the one extending from the 8th to the 18th of December, and the second from December 27 to the 4th of January; in all 50 centigrams of the liquid were used, or 25 in each series. On the 5th of January the animal was inoculated upon the shoulder with tubercle taken from a tuberculous guinea pig. It succumbed one month later with all the typical signs of tuberculosis,—grey confluent granulations in both lungs, a hæmorrhagic hepatisation in the upper part of the right lung, and caseous tubercle in masses in the spleen and liver. This species of guinea pig (angora) usually survives longer than one month, therefore the particular animal presented the minimum of resistance and the maximum of pathological change common to its species, proving that Koch's remedy does not act as a preventive. Another and smaller guinea pig was inoculated at the same time with a portion of the same tuberculous matter; at the time of the report this animal was still alive.

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 68 WARASH AVE.,
CHICAGO, ILLINOIS.

All members of the Association should send their Annual Dues to the *Treasurer*, Richard J. Jungblon, M.D., Lock Box 1274, Philadelphia, Pa.

LONDON OFFICE, 57 AND 59 LUDGATE HILL.

SATURDAY, MARCH 14, 1891.

THE PURPOSE OF "THE JOURNAL."

Our views with reference to the preparation of papers for presentation and discussion in the several Sections at the annual meetings of the Association, as presented in the last number of THE JOURNAL, we trust will not be considered as strictures upon legitimate work. If the humblest member of our profession has a single unknown fact, an observation of value not hitherto recorded, a special method of operation, or a practical suggestion with reference to the action of a remedy or the method of administration of which the profession should be advised, he certainly will not be deterred by what was written from the fulfillment of an obvious duty. But if, on the other hand, one shall be simply ambitious to place himself on record and propose to bring as his contribution the cerebrations of other brains better recorded elsewhere, if from our suggestions he shall deem it wiser to accord the field to those who write of what they themselves have wrought, then the purpose of our writing will not have been in vain. If more and more, in the future, the "Original" department of THE JOURNAL can be made to represent original thought and original researches of our foremost medical men—whose articles it were a credit to publish, and a pleasure to peruse, one of the grandest purposes of THE JOURNAL will be attained.

If, in this connection, the concurrent labors of an able corps of editorial writers can be assured; if the current literature of the day can have ample and judicious representative expression; if the

best of foreign literature can be secured, and the proceedings of medical societies and organizations can be tersely and impartially abstracted, and THE JOURNAL itself remain absolutely divorced from political and partizan purposes, then, if we rightly estimate, will it be prepared to render strong and legitimate assistance in the uplifting of journalism in this country. This is our hope and our anticipation as the future achievement of THE JOURNAL.

We wish to be in utmost harmony with all legitimate journalistic work and workers in the fulfillment of possibilities as set forth in another article in this issue, in which reference is made to the coming meeting of the Medical Editors' Association.

THE MEDICAL EDITORS' ASSOCIATION

This Society, although only a few years old, is practically the most influential and important in the country. Everywhere it is apparent that medical journals are taking the place of volumes and text-books. Medical readers want the latest facts concerning every movement of science, in the laboratory, bedside and hospital practice.

The value of such facts are recognized, not only by the isolated country physician, but medical teachers in crowded cities, and busy physicians, who have little time for reading volumes. While medical journalism is yet in its infancy compared with what it will be in the coming century, its educational power and value is felt in every circle of science. It is fatal to egotism and dogmatic conceptions of theories in science, and points out the fact that no one, however eminent, can fully master all the facts, or apply them in the practice of healing. The formative power of the press is really greater than medical colleges, for it not only shapes the action of educational forces, but it continues through all the after professional life of the student. It is literally a teacher that is always present. The majority of the editors of the medical press realize this power, and use it to promote the higher interests of science.

A small and ever decreasing minority still cling to the idea that medical journals are only valuable in proportion as they serve some personal, selfish ends, or become the organ of a faction or a party. They form their conceptions from the secular press and politics, and it is needless to

say that in the long run they foster conditions which will result in their own destruction. All medical journals have a local personality, and quite naturally give prominence to some college, or teachers, or even a publishing house. But this localism is generally subordinate, and rarely ever assumes the superiority over all others, of its college, teachers or publishing house.

The great art of good journalism is to have a distinct personality, that is broad, clear and generous, above all low levels of impulse and feeling; also to discriminate the value of facts and theories above the authors, or sources; and be able to determine their place and meaning in science. This is an art that must be natural, as well as cultivated, and requires as distinct talents as in surgery, or in other fields of medicine. Among medical journals in this country there are notable examples of great ability in this direction.

The number of journals is steadily increasing, and the process of the "survival of the fittest" is going on with unerring certainty. The standard and editorial tone is rising constantly; a broader generosity and feeling prevails, and scientific kinship is springing up. As the medical press rises in scientific conceptions of medicine, the old rivalry dies away, and the great ocean of undiscovered truth looms up, where each can sail alone, without crossing his neighbor's track, and beyond all contest and rivalry.

The coming meeting of medical editors should include every medical editor in the country. A personal exchange of opinions, and personal acquaintance, are large factors in developing the best interests of each. The day for fulsome admiration, bitter personalities, and hilarious eating and drinking has gone by. The time has come for united work, and every medical editor should join his influence and power to make the Association a true exponent of American medicine. With a united medical press, many of the existing abuses in medical education and charities would be corrected. The low estimate of the profession by public opinion would be a thing of the past. While the Medical College Association and Societies can do much to advance the standard of medicine, a united medical press can do more; this is apparent in the increased quotations of opinions of journals on points of interest.

The profession will watch with increasing interest the coming meeting of the medical editors,

not that they will cause any great revolutions of science, but the more united they become in both personality and scientific interest, the better their work. While science is truly cosmopolitan, every journal and medical man ought to cultivate a National pride and ambition to distinguish facts and principles of medicine as clearly and quickly as foreigners.

Journalism ought to lead and direct the observer to fields of discovery that are as accessible from this country as elsewhere. Concentrate the medical press in work and interest, and the road is open for brilliant discovery.

TREATMENT OF PHTHISIS.

The treatment of disease of the respiratory tract by the inhalation of gases or medicated air attracted attention in the childhood of medicine. The bringing of the curative agent in direct contact with the diseased surface was apparently so rational a procedure that few could doubt its utility, and yet of all the fantastic methods that have been devised, and the various inhalants that have been introduced with such *éclat*, none of them attained permanent popularity. This inhalation treatment of phthisis has ever proved an *ignis fatuus*, leading men into all sorts of pathological sloughs and etiological pitfalls. The discovery of the tubercle bacillus has but added an impetus to the mad race for something that would kill the parasite and not harm the host. Can we hope to kill the tubercle bacillus in the lung by inhalation? Certainly not, because the remedy does not come in contact with the bacillus. The most powerful disinfectant known, unless brought in direct contact with the germ, will not destroy it—if the most infinitesimal part of an inch intervene its action will be prevented. Now if the tubercle bacillus were swimming around in the bronchial secretion on the surface of the epithelial cells we could accomplish something with our disinfecting gas, but unfortunately it is situated deeply in the tissue of the lung, in the giant cell, and often encapsulated in connective tissue. It is apparent that any direct effect that the inhaled gas may have upon the bacilli is due to its absorption, and action through the blood. We do not wish to be misunderstood; it is not claimed that inhalations may not be *useful* in phthisis, the catarrhal conditions and mixed infections that accompany the

disease may be greatly benefited, but they can not kill the bacilli directly.

It would seem that many of our professional friends had lost sight of the etiological factor in phthisis. Are the broad chested, healthy and robust especially prone to this disease, or is it one that is liable to attack the puny, ill-nourished and narrow chested? And are not these conditions favored by over-crowding, ill ventilated school-rooms, long hours of study and cramped positions, with the attendant imperfect expansion and passive congestions of the lungs? Too much analogy has been assumed in the various microbic disorders. Take, for example, small pox, how different are its etiological relations; attacking indifferently the strong and the weak, self-limited in its nature and one attack conferring immunity. If these things were true of phthisis how much more might be hoped for from medicinal treatment? Is it not time that scarlet fever should be brought under control, and its ravages limited, as have been those of small-pox?

We submit our view, and not without trepidation, that the tubercle bacillus will hold its own against all the sulphuretted hydrogen, chloride of gold, pneumatic cabinets, hot air or lymph that can be brought against it. Many of these remedies may prove to be most useful in the treatment of phthisis, but the danger now is that their too enthusiastic advocates will forget the predisposing and exciting causes of this disease and with the inevitable resultant failure will come a therapeutic nihilism, that will work to the discredit of scientific medicine. In conclusion we cannot refrain from calling attention to the words of KOCH, to show how clearly he recognized these limitations when he said: "How far the present methods of cure, mountain climate, open air treatment, etc., may be combined with the new measure is not yet determined, but I believe that these curative factors may be usefully employed in many cases, especially in neglected and severe forms as well as in the convalescent stage."

THE ANTI-TUBERCULOSIS INOCULATION TREATMENT OF RICHTER.

During the past two years, a series of communications has been made to the Society of Biology at Paris, by RICHTER and HÉRICOURT, giving

their results obtained by intravenous injections and inoculations for the relief of tuberculosis. They have not been limited to any one inoculation material, but since April, 1890, their attention has been especially directed to the blood of animals refractory to tuberculosis, as the dog, although they have also used non-bacillar products from old tubercular cultures. They have lately reported that dog's blood has been demonstrated to have a retarding effect in the case of rabbits where tuberculosis has been artificially produced, without, however, arresting the disease altogether. They next undertook to intensify, if possible, these partially protective properties of canine blood, by inoculating a dog with unmistakably active tuberculous matter, in large doses, and one month later, the animal having meanwhile lost flesh and given manifest signs of ill-condition, injected into the peritoneal cavity of three rabbits about 2.4 fluid ounces of this dog's blood. One week later, these rabbits, were with three other test rabbits injected with strong tubercular virus, with this result that in twenty-five days two of the latter were dead, while the others survived. Their next step was to extend the application of their method to tuberculous human beings, using the blood-serum only and injecting it subcutaneously in the interscapular region. This was done early in last December upon four males. RICHTER reported, January 24, to the Society of Biology, that the treatment has appeared to counteract the progress of the disease to some extent, at least, in all four cases; two of whom are affected with pulmonary phthisis, while the other two have both the larynx and lungs involved. Eighteen days after the treatment was begun the physical signs were markedly reduced, night-sweats had been suppressed, and the appetite of the patients had improved, as well as their weight and strength, one of them had gained in weight fully nine pounds in that period; that of the others in a less degree. The laryngeal patients had been relieved of that distressing agony formerly experienced on deglutition, the epiglottis which had been very swollen and motionless had become reduced in volume and regained its mobility. In all the cases, the interscapular region became the seat of itching, some time after the injections, and attained its maximum twenty-four hours later. The size of the dose of injected

serum was stated at about fifteen minims to a fluid drachm, which was administered in from three to six days. No constitutional reaction occurred, and the local disturbance was very slight; pain was complained of after two treatments only.

THE SPHERE OF WOMEN MEDICAL PRACTITIONERS IN CHINA.

The Edinburg Medical Missionary Society publishes, in its quarterly paper for February, 1891, some facts regarding the sphere for female medical attendance among the women of China. Not only is medical skill lacking and of most indifferent quality among the Chinese, but even such as it is it can hardly be obtained by the women, because the native practitioners are males and it is not considered proper for them to treat female patients. Under some conditions an old woman of experience in obstetrical and children's complications may attain to some consequence in a limited locality. But there is a vast female population that has practically no medical attendance whatever; and if the children are included with the women, as they must be to the extent of many millions, the needs of China for female medical attendance will be found to be in the thousands. The number of practitioners who can satisfy these demands can never be supplied from Western lands. The constant aim of all well-wishers of China must be to raise up a supply from among the natives themselves; and fortunately it has already been proved that there is no want of capacity in the Chinese female mind in this direction. Certain difficulties have been, and will continue to be, met in Oriental life and habits of thought, as to women taking a prominent or professional position, especially during young and middle life, but these can be overcome by wise fathers and husbands and by senior female counsellors who have broken away from their old superstitions. In many respects the Chinese are intensely practical, and are not slow to see if a new proposition will pay. This is all that is needed to insure the progress of the movement. The economic wisdom of the people will soon teach them that it is wasteful not to take better care of their women and children, if for no other reason, at least for that which prompts to the care of cattle. The family is much stronger among them than is generally supposed, and

China is the land of the family, in an eminent degree. The pride of country is, also, intense, and leads them to no little exultation when one of their countrywomen has shown herself to be a skilled physician. Western healing has a strong popular hold already. Its results often appear to be almost miraculous; so that by the time a good medical training can be supplied to native women and acquired by them, the demand for them will be sure to be far in excess of the supply.

EDITORIAL NOTES.

SPECIAL NOTICE TO THE OFFICERS OF SECTIONS.—It is not only desirable, but necessary, that those who have in hand the work of securing papers for presentation in the several Sections at the coming meeting of the Association, shall complete their work at an early date. The programmes for the Sections should be in type as early as April 10, and revisions secured at once. The entire programme, thus completed, will be *copyrighted* and published in a single issue of THE JOURNAL, and also in pamphlet form for general distribution. The appropriation of this programme, in whole or in part, by scheming publishers or advertisers, as in times past, we trust will not be attempted.

Officers of the Sections! An important responsibility is upon *you*. The value of the papers which you solicit must largely determine the value of the Original Department of THE JOURNAL for the coming year. Let your selections be well made. Let your work be completed promptly.

SPECIAL NOTICE.—In consequence of the conflict of dates of the American Medical Association and the Indiana State Medical Society, the date of the meeting of the Indiana State Medical Society has been fixed for June 10, 1891, the *second* Wednesday.

CHANGE OF TIME OF HOLDING THE MEETING OF THE NATIONAL ASSOCIATION OF RAILWAY SURGEONS.—On account of the meeting of the American Medical Association at Washington, D. C., on May the 5th, and continuing to the 8th, it has been thought best by the officers of the National Association of Railway Surgeons to change the time of meeting from May 7 to April 30. The meeting will be held at Buffalo, New York, beginning at 10 o'clock A.M., and continuing to May 3. This change will give the sur-

geons who have a long distance to travel an opportunity of attending both meetings on one trip. Remember the change from May 7 to April 30. Any further information desired can be had by addressing Dr. E. R. Lewis, Kansas City, Mo., or Dr. A. G. Guinaer, Buffalo, New York. The meeting promises to be well attended by surgeons from all parts of the country.

NOTICE TO MILITARY SURGEONS OF THE NATIONAL GUARD.—Dr. N. Senn, of Milwaukee, Surgeon General of Wisconsin, is desirous of obtaining the name and address of every surgeon of the National Guard in the United States for the purpose of taking the necessary preliminary steps towards the formation of a permanent National Association.

THE HASSEKI HOSPITAL FOR WOMEN AT CONSTANTINOPLE.—Hospitals are an index of the progress of civilization, their establishment and support always means progress in science and art. We note an excellent description by Pechedimaldji in the *Revue Médico-Pharmacutique* on the Hasseki Hospital for Women, situated in one of the most populous quarters of Constantinople. The sun of humanity is rising upon the women of the East.

KOCH'S REMEDY AND ITS RESULTS.—Under the head of "Progress" in this issue appears an abstract of the proceedings of the Berlin Medical Society, in which Prof. Fürbringer reports forty-six cases of pulmonary tuberculosis that had been under treatment for *more than two months*. The results are certainly not what we had hoped for—three cures and seven deaths. The death-rate in this treatment is proving exceptionally high, and the statistics so far as they are at hand show more fatalities than recoveries.

IMPORTANT NOTICE.—An announcement was recently made that an Army Medical Board would be in session in New York City during April next for the examination of candidates for appointment in the Medical Corps of the United States Army, to fill existing vacancies. At the time of that announcement there were only five vacancies to be filled. Recent Congressional legislation has, however, permitted the retirement of certain officers, so that there are now fourteen vacancies in the grade of assistant surgeon, with the probability that the number will be increased to seven-

teen by the time the examining board begins its labors. As already stated, persons desiring to present themselves for examination by the Board will make application to the Secretary of War, before April 1, 1891, for the necessary invitation, stating the date and place of birth, the place and State of permanent residence, the fact of American citizenship, the name of the medical college from which they graduated, and a record of service in hospital, if any, from the authorities thereof. The application should be accompanied by certificates based on personal knowledge, from at least two physicians of repute, as to professional standing, character, and moral habits. The candidate must be between 21 and 28 years of age, and a graduate from a Regular Medical College, as evidence of which his diploma must be submitted to the Board. Further information regarding the examinations may be obtained by addressing C. Sutherland, Surgeon General U. S. Army, Washington, D. C.

THE MEDICAL SOCIETY OF THE MISSOURI VALLEY will meet at Omaha, Neb., March 19 and 20. Papers will be read by Drs. A. F. Jonas, Omaha; J. M. Emmert, Atlantic; Flavel B. Tiffany, Kansas City; Donald Macrae, Council Bluffs; S. Stewart, Council Bluffs; J. E. Summers, Jr., Omaha; J. F. White, Council Bluffs; S. G. Gant, Kansas City; H. Gifford, Omaha; Rebecca Hanna, Red Oak; and J. P. Lord, Omaha.

RECENT STATUS OF KOCH'S METHOD.—The French and German medical press have devoted a very considerable part of their space for the past two months to accounts of trials and results obtained by the use of the lymph. We have from time to time presented our readers with abstracts of the more important and typical contributions. Their number has now become so large that to abstract even a part of the mass would require vastly more space than the editor has at his disposal. At the same time owing to the wide range of cases in which the remedy has been employed, the great variation in results and the want of uniformity in method of reporting would make any statistical compilation at this time not only useless, but positively misleading. French writers have been skeptical from the start, but some of them report favorable results in isolated cases. This is shown in the abstract, given in "progress" of this week, of thirty-

eight cases of lupus treated in the French hospitals. The German medical press has become more conservative in their claims, and they report many unfavorable effects of the remedy. A careful examination of the communications to date would seem to show that the method has a substantial range of usefulness, though it comes far short of the too sanguine earlier expectations.

MEDICAL ITEMS.

THE MICHIGAN STATE BOARD OF HEALTH.—The recently inaugurated Governor of Michigan is understood to advise the abolition of the State Board of Health, and it is feared by many that the Legislature will act accordingly. It is to be regretted that such an important element in the general welfare of a commonwealth is liable to be sacrificed. The Michigan State Board of Health has for years performed an excellent service to the people of that State, and certainly deserves better recognition than threats of extinction. It is to be hoped—for it assuredly is to be expected—that the intelligence of a State Legislature will not be so myopic and unmanifested as to permit the value of State Medicine to remain unheeded and uncared for.

HOW TO DISPOSE OF A HOPELESS INVALID.—A writer in the lay press has lately advanced a somewhat singular method of relieving the incurable. The plan has certainly the merit of permanency if not that of practicability, or any other winning virtue. Endeavoring to argue from a humane point of view, not only as to the patient himself, but as well those surrounding and intimately connected with the pains and sorrows of the invalid, the writer creates his plea of *kill-ing those so afflicted*. Really, this plan is not new, it has been advocated before, and actually—in earlier ages—put into practice. It is merely noticed here as an example of the ingenuity of the human brain in its effort to meet all conditions of environment, and the extreme views to which those dwelling upon euthanasia may arrive.

HYGIENE IN PHILADELPHIA.—Mr. Henry C. Lea, of Philadelphia, has given a sum of \$50,000 to the University of Pennsylvania for the erection of a hygienic laboratory. The plans have been revised by Dr. John S. Billings, who has embodied in them the results of his observations during a scientific tour in Europe. The institution will, it is stated, be the finest of the kind in

the world—till some other American millionaire builds a grander, or at least a bigger, Temple of Hygiene somewhere else. It is to be provided with lecture rooms, museums, bacteriological and photographic rooms, a crematory, a separate building for the rabbits, guinea pigs, and other animals used for experiments.—*British Medical Journal*.

DRS. SHURLY AND GIBBES.—These gentlemen appeared before the Medical Society of the State of New York, at its fifty-fifth annual meeting held in Albany, on February 3, 4, and 5, and gave a résumé of consumption, as it is considered by them, both pathologically and therapeutically.

THE HARVARD MEDICAL SOCIETY OF NEW YORK CITY, of which mention was made in the last issue, has perfected its organization by the election of the following officers: President, Dr. Rufus P. Lincoln; Vice-President, Dr. Paul F. Mundé; Secretary, Dr. Dillon Brown; and with an Executive Committee consisting of the President, Secretary, Dr. Frederick R. Sturgis, William J. Morton and Henry C. Coe. Meetings are to be held on the first Saturday of each month, except June, July, August and September.

A NEW SCIENTIFIC SOCIETY has just been started at Philadelphia, the main object of which is to examine critically the brains of distinguished decedents. It is said the operations of the society will be limited to persons holding diplomas from the University of Pennsylvania. We trust this is not a masked effort to "boom" a worthy institution of learning.

DECREASE OF LUNACY.—The report of the Commission in Lunacy of the State of New York shows, through the means of improved methods of registration and returns which have been adopted, that there is a material decline in the proportion of lunatics to population. Not alone are the improved records responsible for the more gratifying figures; but the advanced ways of treatment have had no inconsiderable part in the observed result. The term "chronic" with reference to the insane is having a more modified application. Better housing and attention, together with broader views generally, are working factors.

DR. W. W. DALE, a leading physician of Southern Pennsylvania, died at Carlisle, February 26, of pneumonia, aged 74 years.

TOPICS OF THE WEEK.

THE DEBATE ON KOCH'S REMEDY AT THE BERLIN MEDICAL SOCIETY.

The subject of Koch's remedy still continues to be discussed at the Berlin Medical Society every week, the proceedings on February 7 being as follows:

Professor Virchow exhibited the lungs from a case treated at the Augusta Hospital with twelve injections from December 4 to January 12. In each lung, especially the left, were circumscribed areas of dense pigmented carnification, intersected by whitish bands of "dissecting pneumonia" or spaces filled with pus and caseous material. But there was no true caseous hepatization. Another specimen, from a patient who had received thirty injections, illustrated the passage into gangrene of acute "smooth" hepatization. There were large apical cavities, and recent as well as old pleurisy, whilst the lower lobes showed areas of recent catarrhal pneumonia already breaking down. There were numerous healing ulcers in the colon. A third case was one of phthisis complicated with syphilis and amyloid disease; only two injections had been given. The phthisis was acute, and there was extensive cicatrization of laryngeal ulceration. Lastly, he exhibited specimens from a case of hip disease in a child aged three years and three quarters. The head of the femur had been recently excised, and prior to that the child had had five injections. Death occurred from acute miliary tuberculosis, tubercles being well seen in the bone marrow. They also occurred in the lung, and the rare (in childhood) complication of arytenoid perichondritis was present. Professor Virchow deprecated very strongly the statement that in many cases (especially the fatal ones) the injections had been made on experimental grounds and with no therapeutic aim.

Dr. P. Guttman showed a case of inoculated tubercle on the ring finger, in which the diagnostic reaction of Koch's fluid had been confirmed by microscopical examination of excised portions. The "warts" were attributed to inoculation of an abraded surface from a corpse which the man (a hospital porter) was engaged in carrying. Under the treatment they much diminished.

Dr. Grabower had no doubt as to the supervention of fresh miliary nodules in laryngeal cases under treatment, but he did not think this serious; it rather showed that the treatment should be continued. In two cases, which he exhibited, such nodules appeared without any pre-existing disease of the larynx. He gave the details of these cases, both early pulmonary phthisis with bacillary expectoration. In the one laryngeal symptoms arose after the twenty-fourth injection, and examination showed swelling of the false cords and a profuse eruption of grey miliary tubercle. These nodules soon became confluent, but entirely disappeared during the continuance of the injections. The other case was very similar, except that the nodules had not been yet wholly removed. He had often noticed this rapid subsidence of laryngeal tubercle after a few injections, and without denying the possibility of infection by contiguity, he regarded their appearance as a direct indication for persevering with the treatment.

Dr. Jolly, who resumed the debate on Professor B. Fraenkel's paper, directed attention specially to the mental disturbance excited by the fever caused by the injections in some cases, analogous to other febrile "psychoses." He mentioned two cases in Professor Leyden's wards, one a man who had pleurisy with effusion, and who had become depressed mentally by his long illness. The injections 2 to 7.5 mgrs. produced very notable febrile reaction 38.5° to 40° during which he always became dull and confused. After five injections they were discontinued, and two days later he began to have delusions and was transferred to the insane ward, where his delirium continued to increase. However, these mental symptoms disappeared in a fortnight; they were compared by Dr. Jolly to the delirium of defervescence or post-febrile delirium, not infrequently seen. The man was predisposed by his former depression, and by the excitement attending the hopes of cure by the new remedy. The other patient was in an early stage of phthisis but very wasted, and much enfeebled mentally as well as physically. Although very little fever followed the injections there was severe headache on each occasion, so that after four had been given they were remitted for a time. Then they were again used, and he received fifteen more, always suffering severely from pains in the head. He also lost weight. He then lapsed into a state of melancholia with marked delusions. Mention was also made of a hysterical subject who became markedly delirious after each of three injections she received; she had been very delirious previously during the hectic fever of the phthisis from which she suffered. Although such symptoms might arise only in a minority and were seldom permanent, yet occasionally (in predisposed subjects) they initiated an incurable disorder. Hence the need to proceed very carefully with injections in such subjects.

Dr. Henoch spoke unfavorably of the treatment in pulmonary tuberculosis of children, of whom he had treated twenty by this method. Three of these were in the "advanced" stage, but without fever; they were all made much worse, the fever induced by the injections persisting as hectic. Yet only ½ mgr. (at first he only gave 1-10 mgr.) was given at the commencement of treatment, and the largest dose was 3 mgr. In one case there was temporary improvement, dullness disappearing; only, however, to return with increase of other signs on continuance of the injections. Another case illustrated Professor Virchow's statements. A girl 11 years old, whose mother had recently died from phthisis, had suffered from a cough for a year; but there were hardly any physical signs, except slight dullness near spine of scapula, prolonged expiration, and some rhonchi at apices. An injection of ½ mgr gave no reaction. One of 1 mgr. produced next day a rise of temperature to 38.6°, and some râles appeared at the left base. Five injections in all were given, and a few days after the last, signs of extensive consolidation of the left lung appeared; and even after a month's interval they had very slightly decreased. Obviously it was not a mere transitory hyperæmia, but whether caseous or catarrhal hepatization could not be determined. There was some suspicion of commencing

excavation, for the breathing, which was intensely bronchial, had an occasional amphoric tone, and the râles were metallic. Prof. Henoch attributed this change without doubt to the injections. He said not one of his cases had been "cured," not one "improved" except the one which subsequently relapsed to a worse state; and he was embarrassed to decide if he should continue the treatment in children any longer. It would be ludicrous in the case of a child to follow the practice of some physicians who do not use the injections except at the patient's own wish. Bearing in mind the tendency for tubercle in children to be dispersed in many foci throughout the body, he felt one would be justified in only using it with the greatest reserve, and perhaps at no distant date in discontinuing the practice altogether.—*The Lancet*.

SOME MILK STATISTICS.

The *American Analyst* says that there are \$2,000,500,000 invested in the dairy business in this country. That amount is almost double the money invested in banking and commercial industries. It is estimated that it requires 15,000,000 cows to supply the demand for milk and its products in the United States. To feed these cows 60,000,000 acres of land are under cultivation. The agricultural and dairy machinery and implements are worth \$200,000,000. The men employed in the business number 750,000, and the horses over 1,000,000. There are over 12,000,000 horses all told. The cows and horses consume annually 30,000,000 tons of hay and nearly 90,000,000 bushels of cornmeal, about the same amount of oatmeal, 275,000,000 bushels of oats, 2,000,000 bushels of bran, and 30,000,000 bushels of corn, to say nothing of the brewery grains, sprouts, and other questionable feeds of various kinds that are used to a great extent. It cost \$150,000,000 to feed these cows and horses. The average price paid to the labor necessary in the dairy business is probably \$20 per month, amounting to \$180,000,000 a year. The average cow yields about 450 gallons of milk a year, which gives a total product of 6,750,000,000. Twelve cents a gallon is a fair price to estimate the value of the milk, at a total return to the dairy farmers of \$810,000,000, if they sold all their milk as milk. But 50 per cent. of the milk is made into cheese and butter. It takes 27 pounds of milk to make 1 pound of butter, and about 10 pounds to make 1 pound of cheese. There is the same amount of nutritive albuminoids in 8½ pounds of milk that there is in 1 pound of beef. A fat steer furnishes 50 per cent. of boneless beef, but it would require 24,000,000 steers, weighing 1,500 pounds each, to produce the same amount of nutrition as the annual milk product does.—*Dietetic Gazette*.

THE FEVERS OF CHINA.

Dr. Coltman, writing in the China medical missionary journal upon the fevers of China, remarks that but little personal investigation on the subject has been made up to the present time, owing to the comparatively recent advent of foreign medical men, and to the want of confidence on the part of natives to submit for any lengthened period to the treatment of a foreign physician, or

in fact to any one physician, their rule being to change doctors two or three times a day if they can afford it. Again, there have been but small hospital facilities for studying fevers, and there is an impossibility of obtaining post-mortem examinations. Dr. Coltman considers that small-pox is the most common disease, nearly every person suffering from it at some period of his or her life. Vaccination, although practiced, is done very carelessly. Measles appear to be common, but is somewhat milder than in Europe. Scarlet fever, although it undoubtedly occurs among the natives, is far less common than amongst Europeans. Erysipelas is rare. Typhoid fever is very difficult to diagnose in the short time that a foreign medical man is allowed to attend a case; but Dr. Coltman thinks that when more accurate reports are possible, this disease will be found to be more common among the natives than is now supposed. Typhus fever is met with all over North China, and as far south as Shanghai. Relapsing fever is found constantly associated with typhus. Dengue does not seem to be known amongst natives. Cholera occurs as an epidemic every few years, and is very fatal. Diphtheria is severe and frequently fatal amongst the natives. Whooping-cough has occasionally been met with. Rheumatic fever is very prevalent in some parts. Chronic muscular rheumatism is common all over China, but is unattended by fever. Malarial fevers appear to be common everywhere, though the prevailing type varies; thus, tertian is most common in Pekin, quartan in Foochow, Swatow, Shanghai and Hangchow, and remittent in Cheefoo and Tientsin. In Chinanfu Dr. Coltman has never seen a case of quartan ague; it is all intermittent of the tertian or quotidian type. The treatment, of course, of all malarial fever is by quinine or some other cinchona bark alkaloid. In Hangchow the carbolic acid and iodine treatment has been used successfully as a prophylactic; arsenic is recognized as valuable in the chronic form.—*Lancet*.

THE BARRING OUT OF FOREIGN DIPLOMAS BY THE ILLINOIS STATE BOARD OF HEALTH.

This action was taken because: 1. The diplomas of medical schools and universities do not entitle the holders to practice in these countries; 2. As may be seen from p. viii of the "Report on Medical Education" of the Illinois State Board of Health for 1891, the Prussian Staats-Examiner Commission rejected in 1890 more than 40 per cent. of the graduates of the University of Berlin, more than 47 per cent. of the Breslau graduates, more than 31 per cent. of the Griefswald and Halle graduates—and in fact more than 29 per cent. of the university graduates that came before the commission; 3. Many of the rejected candidates come to this country; 4. Many such graduates, fearful of failing in the government examinations in their own countries, come to this country to enjoy a privilege denied them at home of practicing medicine simply on their diplomas; 5. The Illinois State Board of Health feels that it should not place upon such diplomas a higher valuation than is given to them in the countries in which they are granted.

PRACTICAL NOTES

ROTTER'S ANTISEPTIC.

- R. Zinc chloride,
Zinc sulpho-carb. 33.33 grams 45 grains.
Boric acid, 1.80 grams 27 grains.
Sodium chloride, 0.15 gram (2½ grains).
Salicylic acid, 0.33 gram 50 grains.
Citric acid,
Thymol, 33.000 gram 1 grain.
Water, 473.12 c.c.m. (1 pint), ℥.

This solution is used for compresses, irrigation of wounds, etc., in surgery.—*Merck's Bulletin*.

IODIDE OF POTASSIUM IN GONORRHOEAL RHEUMATISM.

Rubinstein strongly recommends in the *Therapeutische Monatshefte* the treatment of arthritides and inflammations of the mucous bursæ with potassium iodide after the following formula:

- R. Potassium iodide, ℥iv.
Distilled water, 5v.

Mix and dissolve. Sig.: Tablespoonful every hour for two or three days.

Amelioration usually begins after three or four doses. Rubinstein reports fifteen cases of acute and subacute gonorrhoeal rheumatism treated in this manner with the happiest results.—*National Druggist*.

TO REMOVE THE PIGMENTATIONS OF PREGNANCY.

In the *Journal de Médecine de Paris*, January 4, 1891, the following ointment is recommended to be rubbed into the affected parts twice daily to remove the pigmentations which so often disfigure pregnant women:

- R. Cocoa butter,
Castor oil, 33 3/4.
Oxide of zinc, gr. v.
Yellow oxide of mercury, gr. ij.
Essence of roses, enough to perfume.

A MIXTURE FOR SIMPLE COLIC.

Dujardin-Beaumetz, it is stated, recommends the following mixture in the treatment of colic:

- R. Strong chloroform-water, 4 ounces.
Decoction of orange-flowers, 4 ounces.
Tincture of capsicum, 2 drachms.

A dessertspoonful of this mixture may be given every fifteen minutes until the pain is relieved.

THE TREATMENT OF GALL-STONES.

Dr. W. W. Seymour, of Troy, in a paper on this subject, after reviewing all the theories as to the possibility of successfully dislodging, dissolving, or otherwise effecting the removal of gall-stones by medicinal agents, concluded with the emphatic opinion that these accretions could not be dissolved, and that all medical treatment for

their dislodgment was likely to prove valueless. He held that operation should be early resorted to in a well defined case, and an exploratory incision should be made where doubt existed. The mortality where the operation was undertaken before complications had arisen was but small, and it should be remembered that post-mortem diagnosis was of no use to the patient and of very little consolation to the friends.—*New York Medical Journal*.

THE TREATMENT OF SYPHILIS DURING PREGNANCY.

Besnier, *Journal de Médecine*, November, 1891, has obtained good results in the treatment of syphilis during pregnancy, by the administration of cinchon wine and syrup of the iodide of iron as tonics, together with nourishing food. The patient also took daily a pill containing one-sixth of a grain of bichloride of mercury, combined with one-twelfth of a grain of extract of opium and one-twelfth of a grain of extract of gentian, the whole rubbed up with glycerine. Iodide of potassium was also advised in amounts of from seven and a half to fifteen grains daily.—*American Journal Medical Sciences*.

TREATMENT OF INGROWN NAIL.

Dr. Pürckhauer moistens the surface of the diseased nail with a luke warm forty per cent. solution of caustic potash, and then scrapes off the softened upper layers with a sharp-edged piece of glass. After a second application of the potash solution the scraping is continued until the nail is as thin as a sheet of paper. It is then lifted up from the soft parts with forceps, and the diseased parts are excised.—*Therapeutic Gazette*.

PREPARATION OF SACCHARIN.

- R. Saccharin, 150 grains.
Bicarbonate of soda, 75 grains.
Distilled water, 9j.

One part of this solution is equivalent to two and one-half times as much sugar.—*Newcastle Remedies*.

UNNA'S TREATMENT FOR RED NOSE.

When red nose is due to acne rosacea Unna gives ichthyol internally in doses of 5 grains, and prescribes at the same time lotions of the same substance in aqueous solution. At night, the following paste is applied to the affected organ:

- R. Sulphur, 5ss.
Rice powder, ℥iv.
Ointment of zinc oxide, 5v.
Mix, and make a pomade.

If the patient is scrofulous or debilitated, he also orders cod-liver oil, syrup of iodide of iron, etc.—*Banaridge's World*.

SOCIETY PROCEEDINGS.

Gynecological Society of Chicago.

Regular Meeting of Nov. 21, 1890.

THE PRESIDENT, DR. W. W. JAGGARD, IN THE CHAIR.

EXHIBITION OF SPECIMENS.—EXTRA-UTERINE PREGNANCY.

DR. C. T. PARKES presented a specimen taken from a case of ruptured Fallopian pregnancy where the history extended back three months, and the symptoms of rupture to three weeks. But three days had elapsed since the operation, and therefore the outcome could not be told.

The second specimen was of a fibroid uterus, removed through the vagina in August last. Electricity had previously been thoroughly tried, but without effect. Upon incising the specimen a small intra-uterine fibroid was found projecting internally, and which could not be canterized by the intra-uterine electrode.

DR. KARL SANDBERG first offered a specimen of large sized ovarian abscess.

Next was a supposed papilloma of the ovary, removed from a girl sixteen years old, where there had been a history of much pain with marked enlargement of the ovary—since an attack of scarlet fever four years previously.

The third specimen was a tube and ovary apparently normal, but which, from an incomplete history, was evidently the source of the debility and retardation of convalescence from parturition ten months before.

A fourth specimen showed pyo-salpinx, removed three weeks previously. This also followed the puerperal state, and was evidently producing an altered condition of the mind. Since operation, however, all appearances of insanity had disappeared.

DR. HENRY P. NEWMAN read a paper entitled THE REMOTE RESULTS OF SHORTENING THE ROUND LIGAMENTS FOR UTERINE DISPLACEMENTS BY THE NEWER DIRECT METHOD.

After reviewing a few of the technical points of Alexander's operation, particularly with reference to the initiative steps of finding the chord by deepening the wound to the aponeurosis of the external oblique, and referring to the acceptance of a new method first suggested by Dr. J. Frank, of Chicago, the claim of calling this the "direct treatment" was defended by the following distinctive advantages, viz.: 1. The single sweep or two with which we cut down upon the inguinal canal or the glistening aponeurosis of the transversalis muscle, directly over the internal ring, or canal of Nuck. 2. Through a single nick in

the course of the reflected fibres of this aponeurosis the blunt hook may often be passed into the canal and the round ligament pulled out in less time than it takes to tell it; or, by lengthening the incision, it may be exposed along the canal in its entirety. 3. There can be no doubt here of the identity of the ligament as a duplication of the peritoneum is seen surrounding it at its abdominal extremity. 4. The force used in pulling out the ligament is both brought to bear upon it at its strongest portion and is in a direct line with its intra-abdominal course. This is in strong contrast to the old mode of pulling upon its frayed-out terminal fibres at an acute angle with its inner and stronger portion and over the sharp, resisting surface of the ring. 5. Aided by the sense of sight, and seizing the ligament above the inguinal canal, we can feel assured that we are drawing upon the abdominal portion of the ligament, and not merely stretching its inguinal section. 6. As there are few or no adhesions at this portion, there should be absolutely no tearing of the tissues. Consequently, where aseptic methods are used, there should always be healing by first intention, and drainage and after treatment be relatively simplified. 7. Where the ligament is strong and fully developed, as it is in its upper portion, it can be more securely anchored or made fast to the surrounding tissues. 8. Hernia is guarded against by deep sutures constricting the canal about the internal ring, insuring firm union where most needed. 9. The intercolumar fibres and tissues about the internal ring are not interfered with or irritated in any way.

The histories of seven cases were given wherein the operation of abbreviating the round ligaments had been performed. In all the cases two years or more had passed since the operation, and the results were shown to be highly successful. In three cases there was retroversion with prolapsus of both uterus and ovaries; in one procidentia with enlarged, tender ovaries; and the remaining number "presented the usual menstrual disorders indicative of the severer types of uterine and ovarian displacements, and were upward of ten years' standing."

DR. A. W. ABBOTT, of Minneapolis, Minn., reported nineteen cases in which he had done the operation up to November, 1888. All of them were for retroflexion, and not for prolapsus. The Alexander method was closely followed, and without the difficulty described by some. He believed that if Dr. Alexander's directions were followed implicitly the operation would be found simple and easy; at the same time he would not disparage Dr. Newman's ideas. Of his nineteen cases in thirteen the normal position of the uterus is maintained, and of these eleven stand improved, and two unimproved. Of those in which the position is not improved, six; in three the symptoms are improved. Of the total number of operations,

* Abstracted for The Journal.

the symptoms have entirely disappeared in ten, in four they are improved, and in five not improved at all. Dr. Abbott believed that the results were far better in the parous state; and that manifest adhesions, or the slightest history of a former peritonitis should preclude operative measures.

DR. F. H. MARTIN reported the same number of cases as Dr. Abbott, and contended strongly for a proper and thoroughly cautious selection of cases. In cases that were well selected the justifiableness of the operation had been well demonstrated. Dr. Martin believed the operation was well indicated in those cases in which the uterus allowed of replacement and retention by a well-fitting pessary, and that it is only in such cases that it should be done.

DR. T. J. WATKINS had performed the operation a limited number of times, and had had an opportunity of observing its results in a large number of cases. "None of these," he says, "were called therapeutically cured, but in many of them an alleged anatomical cure resulted. The suffering in these so-called anatomical cases is caused, in my opinion, either by adhesions, by mal-location of the uterus, or by continuous strain upon the shortened ligaments, that is, muscular strain."

DR. H. P. NEWMAN, in closing the discussion, said: "There will always be failures in this operation where it is done for indications that Alexander's operation is not claimed to cure. Where done as a conservative operation for restoring ovaries, their condition not being definitely known, there is always an element of uncertainty and always a possibility of failure; but the failure should not be referred to the operation, but to the judgment of the physician. In regard to the method I have brought forward, the points that I have stated, I think, are well taken, and, if put in practical use, will perhaps be better realized than they can be by simply hearing them tabulated here."

DR. BAYARD HOLMES read a paper having the title

THE TREATMENT OF ACUTE ANÆMIA BY INFUSION.

After barely touching the history and uses of transfusion, Dr. Holmes struck out with the statement: "Death from hæmorrhage is due to anæmia of the brain;" and "fatal anæmia may be either quantitative or qualitative." The author then dwelt upon the physiological state and quality of the blood, and the loss, both in volume and constituency, which could be sustained before reaching the fatal point. And in considering the loss of blood as the cause of death in obstetrical and surgical cases, as well as in accidents, and as a factor in protracted convalescence, he felt that its best mode of treatment should be well recog-

nized. If one-half the volume of the blood was to be found in the collapsible veins, it was quite evident that they would be first emptied in profuse bleeding. If an anæmic patient be placed in a vertical position, with the head down, the vessels throughout the three vital parts, viz., the brain, heart, and lungs, will be freely distended with the least amount of blood, and therefore the first indication in severe acute anæmia is to procure and maintain this decubitus. Bandaging the extremities would have quite the same effect.

When these measures fail to meet the requirements of the case, the recourse to the infusion of a neutral salt solution will be found necessary. The amount of salt solution, as well as its concentration, was of some moment. Yet it is not unlikely that the establishment of a quantitative equilibrium will prove but temporarily a relief, inasmuch as the oxygen-carrying and nutritive needs of the circulation are not thereby met. It is then the desired result may be won by the transfusion of defibrinated blood.

The paper concluded with the following aphorisms: 1. In dangerous acute anæmia auto-transfusion should first be practiced. 2. When the lymph spaces are drained, as is indicated by the sunken and drawn appearance of the face, or by the time auto-transfusion has been tried and the symptoms of anæmia persist, infusion of a large amount of 0.6 per cent. salt solution should be practiced. The necessary apparatus is so simple and the danger so remote that this measure should not be neglected. 3. The immediate intra-vascular injection of salt solution or blood for acute anæmia cannot be countenanced in the present state of our experience and knowledge. 4. The value of secondary subcutaneous or intraperitoneal injection of blood in cases of so extensive hæmorrhage that a qualitative anæmia is present after the mechanical needs of the circulation are satisfied, is still conjecture, but certainly such injection of blood should not be practiced until reaction is well restored. 5. The immediate subcutaneous injection of blood diluted with a large amount of salt solution is not contra-indicated, but its value is still problematical. 6. The rotary surgical pump is the most perfect and manageable apparatus yet proposed for subcutaneous infusions and injections of large amounts, and for direct intravascular transfusion.

DR. PARKES desired to ask the author what local effect the introduction of a quart of the solution had. He referred to two instances where a large quantity of the salt solution was injected to exsanguinated patients, in both of which good results followed.

DR. F. H. MARTIN commended the apparatus exhibited by the author of the paper. He also spoke of the very favorable results in a case under his care.

THE PRESIDENT mentioned the effect of a pro-

fuse hæmorrhage, and spoke also of the subcutaneous use of the salt solution in a case of profound collapse, and where an almost magical effect was produced.

Philadelphia Electro-Therapeutic Society.

WM. H. WALLING, M.D., SECRETARY.

The February meeting of this society was held at 36 N. Nineteenth St., February 8, PRESIDENT G. BETTON MASSEY, M.D., in the Chair. The minutes of the last meeting having been read and approved, and the Treasurer's report having been received and accepted, the society went into the election of officers for the ensuing year, with the following result:

President, Dr. Matthew W. Grier; Vice-Presidents, Drs. I. P. Willits and Horatio R. Bigelow; Secretary and Treasurer, Dr. Wm. H. Walling; Executive Council, Drs. G. Betton Massey, J. J. Taylor, and W. H. Walling.

DR. MASSEY then read the following paper:

ELECTRO-PUNCTURE OF A CYSTIC GOITRE; DISAPPEARANCE OF BOTH CYST AND GOITRE.

A maiden lady, aged 41 years, was brought to me by Dr. Emily W. Wyeth, Oct. 1, 1889, with an irregularly shaped goitre, about the size of a small orange. The left lobe was much the larger and was the seat of a monocyst of considerable proportions, which had increased very much during the last year, the growth having been noticed about seventeen years. The circumference of the neck at this point was sixteen and three-eighths inches. Treatment was begun by a negative puncture of the cyst with a solid needle, 35 milliampères being used for fifteen minutes. This was followed by a considerable oozing of a straw-colored liquid. Four days later the cyst was evacuated of its contents, measuring an ounce and a half, and 40 ma. negative applied to the cyst walls for ten minutes, by means of the canula acting as an electrode, the latter being insulated as far as the cavity. This procedure was repeated five times subsequently, with current strengths rising to 100 ma., the cavity being permitted to refill after each puncture. Careful measurements showed that the cyst was refilling more slowly after each application, but on Dec. 9 it was decided by Dr. Wyeth and myself to make a free opening and apply the positive pole, by means of a gold bulb electrode, to all sides of the cavity at stated intervals, maintaining free drainage in the meantime. This procedure was required but twice, with currents of 100 and of 50 ma., the drainage-tube, which was most assiduously looked after by Dr. Wyeth, being gradually shortened and removed on the seventh day. During this time the patient suffered a slight rise of temperature, due to a temporary obstruction of

the discharge by accidental removal of the tube. By February 21 nothing remained of the growth but a cicatricial lump about the size of a peach stone, and two months later this had also disappeared without further treatment.

DR. GRIER: Has never treated the cystic variety, but has used outward applications on true goitre with currents of not over twenty-five ma. He used tin electrodes covered with muslin, placing the positive pole on the inferior cervical ganglion, and two negative plates upon the tumor, one on each side. The sittings lasted for five minutes each, being repeated three times a week, for from two to three months. Some preparation of the iodides was also used. Favorable results were obtained in about fifty per cent. of the cases.

DR. PETERSON spoke of a case in which the fluid extract of ergot was used, with good effect, being applied to the tumor upon the positive pole.

DR. BIGELOW: There is a canton in Switzerland in which you cannot walk out without meeting a goitre. The disease is not confined to those who drink the waters, neither to those who carry heavy burdens on their heads.

DR. BIGELOW could not see why the same treatment should not be followed in a fibroid in the neck, as well as in any other part of the body.

In a cystic tumor the action of the current was: 1. Electrolysis. 2. The arresting of secretion, and 3. To compel absorption. He also thought that constriction should act well in such cases. Neggath uses the faradic current in overcoming ovarian cysts. He applies the negative pole to the ovaries, per vagina, and the positive on the abdomen, using swelling currents for an hour at a sitting, obtaining good results in six weeks. It must be the heavy voltage that acts so favorably, and if in one case, why not another?

DR. GRIER had used faradism in goitre, but abandoned it on account of its unpleasant effects.

DR. WALLING: Dr. Massey says that he emptied the cyst before applying the galvanic current. We must be guided by experience, as well as by theory. Why was the positive used? Was not the negative pole the one indicated? In the treatment of hydrocele, Dr. Walling does not drain the sac, unless it is extremely distended, and then but little. Use the negative needle in the tumor, and the positive on the thigh, with a current strength of fifteen ma. for fifteen or twenty minutes. He had excellent results in such cases. Scarcely any inflammation followed, and the contents of the cysts were rapidly absorbed, with obliteration of the sacs.

He had used the strong faradic current, but saw no benefit from it, although it caused strong contractions of the muscles. Why not treat other cysts in the same way? You cannot reach all parts of the surface of the sac, after emptying it, while some parts would be unduly acted upon,

tending to set up too much inflammation. What better electrolytic than the fluid in the sac, thus reaching every portion alike.

DR. MASSEY said he was disposed to regard the faradic current as of no value in cystic tumors; but in one case, where a cyst developed in a fibroid, he used a strong faradic current with great advantage. Heregarded aseptic aspiration, followed by electrolytic puncture, as the best procedure in cystic conditions.

FOREIGN CORRESPONDENCE.

LETTER FROM LONDON.

(FROM OUR REGULAR CORRESPONDENT.)

The Physical Advantages of Abstinence—The New Fashion of Naming Bazaars—What a Spell of Severe Weather Cost the Metropolis—Low Death-Rate in the British Army—The Gull Studentship in Pathology—Ether Drinking in Ireland The Barber-Surgeons of London—Female Nursing Service in India—Dr. Koch has a Rival at Edinburgh.

At a meeting recently held for the consideration of the physical advantages of abstinence, the chair was occupied by Dr. B. W. Richardson, who in opening the proceedings detailed some of the researches which he had made at the instance of the British Association in 1863, when he was requested to continue his inquiries into the action of various chemical substances on animal bodies. His observations led him to the conclusion that the effect, even in strict moderation, of alcohol was invariably to reduce the temperature of the body, whilst it neither tended to promote its muscular development nor strengthen its vital power. Dr. Norman Kerr directed his remarks chiefly to young men, and he pointed out that the habitual use of alcohol led to the augmentation of the non-reasoning connective tissue of the brain, with the consequences that there was found to be a perceptible dwindling of and alteration in the shape and power of the reasoning cells of the mind, and he thought that the best physical condition was only to be attained by uncompromising total abstinence from all intoxicating liquors.

In accordance with the new fashion of naming bazaars like dramas, or tales, or other works of art, the title "A Dream of Health for Sick Children," has been hit upon for one at which all of the stalls will represent scenes from the works of Charles Dickens. The bazaar is to be held under royal patronage at Kensington Town Hall, in aid of the fund for furnishing the Convalescent Home for the Victoria Hospital for Children at Broadstairs, Kent. A special feature will be a stall devoted to dressed dolls. Any dolls not disposed of

at the bazaar will be distributed among the children of the Victoria Hospital, Chelsea.

They are now able to tell approximately what the late spell of severe weather has cost the metropolis in lives lost. The first distinct increase of mortality due to the cold was shown in the record for the week ending December 20, when the death-rate had jumped from 21.1 to 26 per 1,000. It reached its maximum, 29.7, on January 3, and the last week of the frost it fell to 25.7. For the six weeks the average rate was nearly 27.7, an increase over that hitherto prevailing of rather over 1.5 per 1,000 per annum. What this means applied to the 3,815,704 inhabitants of London embraced in the returns is that frost, snow and fog have carried off about 2,860 victims in the six weeks. It was a curious circumstance that during the same period zymotic diseases were less fatal than usual.

The death rate in the British Army, as compared with those of Germany, France, Austro-Hungary and Belgium, is extremely low. For last year the death rate of the British Army was .86 per cent. of the whole, whilst Dr. Corput, who has been charged by the Belgian Government to examine the sanitary institutions of Germany, states in his report that the annual army death-rate of Germany is 3.97, of Belgium 4.07, of France 5, and of Austro-Hungary 5.95 per cent.

Sir William Cameron Gull has founded a Gull studentship at the Medical School of Guy's Hospital, with which his father, Sir William Gull, was so long and so honorably connected. The studentship will be of the yearly value of £125, with a further allowance of £25 for apparatus. The appointment will be tenable for three years, and may be renewed for two years more. The student will not be selected by examination and the appointment will be open, though preference will be given to a suitable candidate from Guy's Hospital. The foundation will worthily commemorate the late Sir William Gull's love for pathological studies, as well as his long tenure of office as physician to Guy's Hospital.

Never, perhaps, has the direct relation between death and overcrowding been more strikingly presented than in a little table compiled by Mr. C. Roberts, and included in an article by him in the new paper entitled *Physique*. It relates to the sanitary districts of London, and shows, among other suggestive facts, that whereas in Hampstead, where the allowance of space is 180 square yards to every inhabitant, the death-rate is only 10.5 per thousand per annum, in the Bethnal Green condemned district, where the allowance is 13 square yards only per person, the death-rate is just 40 per thousand.

Ether drinking is practiced largely throughout many districts of Northern Ireland, notably in Derry and Tyrone. According to a Government report, some 100,000 Irish consume 17,000 gal-

lons of impure ether annually, and it is proposed to counteract the baneful habit by introducing naphtha into all ether sold otherwise than medicinally, or else to limit the sale to chemists.

In these days of higher development of the medical art, the idea of associating surgeons with barbers is apt to raise a smile. But however widely the ways of doctors and barbers may now differ, there was a time when the wielders of the lancet were allied by the most solemn ties to the manipulators of soap and razor. The records of the ancient city guilds show how jealously the privileges of these members of society were formerly guarded, and in perusing the volume of "Annals of the Barber-Surgeons of London," compiled by Mr. Sidney Young, one may gain a more particular knowledge of the history of a venerable yet utilitarian craft. The author points out that the barber-surgeons were a professional rather than a trade guild, and their company stood alone as the pioneer of technical education. As long ago as the middle of the fifteenth century the company provided surgical lectures and systematic instruction for its members. Museums, libraries and anatomical theatres were established, and a valuable amount of lasting work was done which benefited the Kingdom at large. Mr. Young holds that the barbers were banded together as early as the thirteenth century. The first record of the company's existence as a trade society bears the date of 1308. The barbers performed many of the minor operations of surgery, such as bleeding, tooth drawing and cauterization. Up to the twelfth century the only reliable surgeons were the clergy, but the Council of Tours held that blood-letting was incompatible with the office of priesthood. At the present time the chief treasure belonging to the Company of the Barber-Surgeons is the well-known famous painting by Holbein, 10 ft. 2 in. long by 5 ft. 11 in. high, which represents either the granting of the charter by Henry VIII or the Royal assent to an Act of Parliament uniting the Barbers' Company with the Guild of Surgeons. The picture is painted on oak panel, and contains nineteen figures. Mr. Young has much that is interesting to say concerning the property, charities, plate, pictures and general features of the Company as it exists to day.

Through the instrumentality of Sir Frederick Roberts, the Government of India has organized a "female nursing service" for the army hospitals of that country. The nurses to be employed are, it is said, ladies who will be required to show that they have undergone training for at least twelve months in a civil hospital in England in which male patients receive medical and surgical treatment. The scheme constitutes a modification of that inaugurated by Lady Roberts. The number of nurses to be employed will be fixed by the Government. For administrative purposes

the service will be divided into four circles, each under a superintendent, with their headquarters at Meerut, Rawal Pindi, Bangalore and Poona.

Dr. Koch has just reached the age of 42. His father was a mine manager, and young Koch had a hard struggle in his profession. Having passed through the university, he finished his medical education in Hamburg Hospital, and then started as a country doctor in Hanover. He was restless in the provinces, however, and changed several times before he landed in Berlin.

Dr. Koch has a rival in Dr. Russell, of Edinburgh, and Dr. Russell in his turn has a rival in Dr. Stills. A Scotch paper says that considerable discussion has been aroused through a rumor having gained currency to the effect that Dr. H. I. Stills had arrived at the same conclusions as Dr. Russell concerning the extermination of cancer some time ago, and was only awaiting further confirmation before announcing it.

SPECIAL CORRESPONDENCE.

Legal View of Insanity Commitments.

To the Editor:—In reference to your editorial citation of David McAdam's (at present Judge of the Superior Court of New York) "Legal View of Insanity Commitments," permit me to state that they have become a laughing-stock among all judges, lawyers and physicians who have any knowledge of the subject-matter, or familiarity with the daily and hourly emergencies to which the physician called upon to deal with the problems of insanity is exposed. His loud and positive declarations were the outcome of an agitation of the subject, provoked by the publicity given to the commitment of one of my private patients. The learned judge has construed for himself a remarkable dilemma. On the one hand he states that his judicial action added no force to the commitment, and that he had indulged in this action in 7,000 cases, on the other he—or at all events the Court over which he presides—becomes the medium to give publicity to what a certain sense of propriety which has thus far appeared to guide our judges, regards as a private, family matter. That the judge assumes no responsibility is correct; it is the physicians who are responsible, and whom the law registers the responsibility of by compelling them to comply with the existing legal forms. It is to be

hoped that—not further hampering legislation, as a few demagogues in our State Senate are attempting to impose—but some measure be adopted to protect physicians against such outrageous and libellous publications as the indiscretions of the legal officers exposed them to, in the very case which led to Judge McAvlan's gratuitous farago.

E. C. SPITZKA, M.D.

New York, February 26, 1891.

The Treatment of Carbuncle.

To the Editor:—Under the head of "Practical Notes" in a recent issue, we will all agree with Dr. A. P. Brown in his treatment of carbuncle, as far as crucial incision, use of cocaine, and packing with salicylic acid are concerned; but as for applying a *dirty ointment* to an *open wound* the modern surgeon will most decidedly disapprove of. A better procedure would be, first scrub with soap and Hg Cl₂ 1:1,000, anesthetize with cocaine, incise, curette, swab with tr. iodine, pack with iodoform gauze and apply a *moist* dressing of Hg Cl₂ 1:5,000 or carbolic acid 1 per cent.; the latter will lessen pain. Remove dressing once in a day or so, and reapply tr. iodine if necessary and proceed as before.

RALPH CHANDLER, M.D.

135 Grand Ave., Milwaukee, Wis., Feb. 27, 1891.

Shall The Journal be Removed to Washington?

THE ACTION OF THE McLEAN COUNTY MEDICAL SOCIETY, BLOOMINGTON, ILL.

To the Editor:—The following resolutions were unanimously adopted at the regular monthly meeting of the McLean County Medical Society, Thursday, March 5, 1891:

WHEREAS, There is an effort being made to remove THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION from Chicago to Washington, D. C.

WHEREAS, The American Medical Association is no sectional body, and when we consider Chicago from its geographical location, so readily accessible from all parts of our country, it being the greatest railroad centre in the world, its unsurpassed mail facilities, and destined to become the greatest medical centre of our country, also in wealth and population.

Resolved, That the Members of the McLean County Medical Society cannot see what advantage THE JOURNAL could possibly gain by its removal to Washington, but believe that such removal would be detrimental to THE JOURNAL and interests of the Association, and be it further

Resolved, That the delegates elected to attend the next meeting of the Association do all in their power to oppose the removal of THE JOURNAL.

G. M. SMITH,
RHODA GALLOWAY
F. J. PARKHURST Committee

To the Editor:—I have always felt the deepest interest in the creation of a journal that would represent the medical living age: around which would be rallied the most cultured minds and ardent efforts of the medical profession in this nation, and which should represent, besides, the most advanced thinkers and workers in all the world. When, therefore, the proposition was brought forward to create THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, I became its enthusiastic supporter and predicted, confidently, its future triumph as the representative of the medical interests throughout the country; and now my judgment is, that it has done well—reflecting great honor upon its editors, the Board of Trustees and Chicago, where it has been so well carried on. Nevertheless, I am bound to say that, in my belief, the managers have been so conservative, so determined to take no risks that involved a prospect of pecuniary embarrassment, that THE JOURNAL has been kept too much in the rear of the line of a contest for the due rank of medicine in communities and in the State. It has not, I think, been full enough of an aggressive

spirit; nor has it presented early, and in a compact form, the medical progress at home and abroad. The great reason for this, I am sure, has been that the managers have never felt willing, or, I might say, able—to select a highly competent editor, who should direct its way and be held responsible for a high character of work.

No one doubts the editorial capacity of Dr. N. S. Davis, or Dr. Hollister, but these gentlemen, both are large practitioners and could not have afforded to give their entire time to so exacting a situation. Hence THE JOURNAL, excellent and able as it is, has not attained to the exalted position of the leading journal of this country.

Now, this is what THE JOURNAL must become to be commensurate with the spirit and demands of our profession here. Thus far THE JOURNAL has stood only as the child of the Association—nursed by it—not self-dependent, but sustained by the funds remaining in the treasury after all other claims had been satisfied. But now a new state of things should be inaugurated. THE JOURNAL must lead and sustain the Association; it must earn the necessary sums to give to it the broadest character and most elevated rank in the promotion of scientific medicine, and its due social and political influence in the State. It must be able, by its great strength and activity, to fuse into one mass the intelligence, feeling and force of our vast faculty. Our obligations to society are continually increasing; the elevation of the social and political State requires, in a great degree, our cooperation.

The time has come for medicine to demand a place in the administration of the most important affairs. We must insist on the creation of a Secretaryship of Public Health, as fully empowered with responsible duties as any other in the Presidential Cabinet.

I suppose that this proposition will be met by derisive jests and supercilious exclamations; nevertheless, the fact remains that there is no other profession that excels ours in positive efficiency to sustain public order, comfort and virtue. We have vast capacities for the direction of society and the promotion of human happiness. At this time I cannot dwell but in a general way upon this topic. Give us the power to direct all that which constitutes hygienic laws—the control of the mode of living of the people; e.g., to secure unadulterated food, pure water, ample light and air space in their dwellings, drainage, disposal of excrement, garbage and offal of every description, regulation of the hours of labor, the protection of childhood from severe toil, quarantine against pestilence, isolation of infectious diseases, the disinfection of certain localities, the overcrowding of school rooms, the abuse of the brain in teaching, the prevention of marriage in hereditary diseased types of constitution and in cases of near consanguinity, the care of the sick, and of the insane in special and general hospitals, and the regulation of those two giant evils of civilization, intemperance and prostitution.

At this moment the profession is manifesting, in a higher spirit than ever before, the purpose of suppressing contagious and infective diseases. This work was begun by Jenner, a century ago, and the awful scourge of small-pox has been nearly stamped out, wherever vaccination is compulsory. We have now assumed the stupendous task of suppressing all the terrible diseases that desolate the world. To accomplish all this we ask for the facilities of the government and the power of law. We must assist, also, in the formulation of appropriate laws and in their effective application.

I affirm that the medical profession is worthy of full recognition by the State in its Councils and by its resources to carry forward its beneficent work. Moreover, our profession lives closer to the heart of humanity than any other. We are bound to lavish our consolatory art upon all races and ranks of society, alike. We cannot abandon the lowest, most degraded, the poorest and most criminal of our fellow beings. We cannot shrink from impact with the pestilence, or the terrible ordeal of battle. It is not the bugle note of "forward," the advance

of the standards, or the roar of the conflict, that excites our enthusiasm; it is the cries of the wounded and dying, the fearful ruin of the field that sustains our energies in the smoke and flame of battle.

During all the dread scenes through which we have so lately passed, the physicians on both sides gave their best services to friend and foe alike; and, when the conflict was over, they were the first to extend the fraternal hand across the red field of war. It is my opinion that, to-day, the strongest bond of union in these United States is the medical profession, founded upon their high order of culture in the "humanities," in science, and that deep sense of sympathy and good-will to men, which makes war abhorrent.

We are often discouraged by seeing our advice disregarded, and feel that our profession does not command properly public confidence. Our opinions, it is said, are unreliable in comparison with other learned professions. We declare this to be unjust. We do not claim that medicine is perfect; we feel its deficiencies; yet we know that a steady and brilliant growth exists, and that, in every respect, we are abreast with other professions. When we compare our opinions with those of lawyers, theologians, statesmen, merchants, manufacturers, civil engineers, etc., we find that all these are tainted with as much uncertainty as our own. Why should not scientific medicine be of equal certainty? We employ the same logical processes in solving the problems of disease as those made use of by all investigators in serious questions. We employ the methods of the calculus in clinical investigations, like those followed by astronomers in solving the problems in celestial mechanics.

Hence, it seems to me a duty on the part of the medical profession to strive for a substantial representation in the Cabinet, in the Senate and House of Representatives, in Congress, by men who shall be distinguished for professional ability and general knowledge of affairs. We know the exalted position held by Rush in the Continental Congress. Since his day a number of distinguished medical men have sat in the Senate and in the House, but their number has decreased since the rancor of partisan politics has become so bitter and the glut of wealth has pushed aside the most capable men, because they have not a money power to back them.

In the British Parliament we see a steady increase in the medical representation. Trousseau, Paul Bert and Nélaton were Senators of France. Virchow has served in German, and Semmola in Italian Parliaments. Who, that recalls all the qualities of Gross, Ewe, Flint and H. Campbell, can doubt the high rank they would have held in our Senate. The influence of our Association accomplished the elevation of the surgeons of the Army, Navy and the Marine Corps to increased rank and pay.

In regard to the location of THE JOURNAL.

We are all proud of the greatness and splendor of Chicago; she is a wonder of the world; for certainly, no city in the world's history has had as rapid a growth and has so fully developed and maintained as massive a trade in manufacturing and mercantile pursuits. Moreover, it is plain that in the arts and sciences she is making rapid progress—aiming to make the place a seat of learning as well as of commerce. No one can visit that wondrous city and become involved in the ebb and flow of her busy streets, travel through her great avenues and parks, without seeing the most convincing proofs that her stupendous affairs are being directed by minds of vast capacity and activity.

Nevertheless, the consciousness of Chicago is not equal to the consciousness of the Nation—whose central point is Washington. The correspondencies of the latter are illimitable. All roads lead to the Capital; *there*, is our father's house, and *there* we are all at home.

The assumption of our higher claims for social and political recognition must first be made good *there*, in order to make them successful; and THE JOURNAL of the

Association shall become our potent advocate. Nowhere else can it exert so great an influence—neither at Chicago, New York nor Philadelphia. I pray our brothers of the Northwest—of which Chicago is conceded to be the capital—to give their good-will to this new movement; not forgetting, though, the honor which Chicago has given to the foundation of the Organ of the Association.

No one of a generous nature, I hope, will asperse this movement towards Washington as one that will lower our noble profession to the plane of common politics. No, we despise the intimation: the politics we shall struggle to develop will be the elevation of medical administration to its proper place as an integral part of public affairs for the promotion of public well-being.

If a general and hearty consent to the removal of THE JOURNAL from Chicago to Washington shall have been agreed to, then the general business management of the Organ and its editorial work will become most important subjects of consideration.

The business management is of the first importance; not second, I think, to the purely editorial; but both must be made the strongest possible and cooperative; and the gentlemen who obtain these places must be paid sufficiently to give THE JOURNAL their entire time. I mean that they shall have no other employment—Governmental or otherwise. In fact, as I see it, their duties shall absorb all their capabilities; and in the editorial work, more especially, large assistance will be required.

In order to secure the best talent for the editorial department, more funds than are now at the disposal of the managers, must be provided. I propose, for this purpose, that an appeal be made to the members, at large, for a loan of \$10,000, in sums of \$50 and \$100, to be returned in due time with interest at 3 per cent. If one hundred persons can be found who will thus loan \$100 each, it will meet the appeal. Professional hope and pride will surely answer such a call, promptly. In this way the whole present income could be devoted to the enlargement of the paper.

The profession in this country needs a journal as great in size and in capacity as that of the British Association. We have the men, the money, and certainly the patriotism. It must and can be made so strong as to become indispensable to the practitioners in our land.

It will become, in no wise, the overpowering rival of our present capable and ably conducted local journals; it will not deprive them of their patronage, professionally or in a business way; and I hope that gradually, it would be able to drop the greater part of its advertisements.

Every practitioner knows that his greatest success depends upon his standing in his own community; so his best productions must be made known to his professional brothers at home. But there are subjects about which he may desire to address the profession at large; in that case THE JOURNAL of the Association would be his vehicle and give him an audience commensurate with the nation. Proceedings of the leading medical and scientific societies, and reports of the great general hospitals, should be promptly displayed in its columns; and the subscribers would, in this way, become furnished with the work of eminent men, here and abroad. Careful reviews of new books should also be produced. It seems to me that not only local journals will be better patronized, but the proceedings of State and local societies will become much more valuable.

In short, when THE JOURNAL shall have been fully equipped, the subscribers shall be kept *au courant* with the progress of medicine in all the States and cities at home and abroad.

We have, in the famous journal of the British Medical Association, an example. It struggled from 1854 to 1867 on the same plane, nearly, as ours; but, when in 1867 Ernest Hart was made editor-in-chief and Francis Powke its business manager, its whole career was quickly changed; the quantity of its printed matter was, at once,

increased and has been more than doubled, so that, now it prints 3,000 pages a year, and its contents include the whole progress of medical science. Its subscription list is about seventeen thousand, and its annual income, including advertisements, is over \$100,000. Its surplus income has accumulated, I understand, to some \$200,000, the interest of which is employed in many ways, to enlarge medical culture and take care of professional interests in the government. The influence of such a medical organ, and its power for doing good is incalculable. When, during the past year, the General of the Army, Lord Wolsley, issued a general order, the operation of which was sure to lower the status of the medical corps, *The Journal* promptly but respectfully protested against its execution and secured its modification.

Our great Association, many are saying, has been gradually losing influence in the profession at large. A slow and somewhat insidious disintegration has been manifested for some time past. I have heard it said that, with the death of its eminent founder, there is great possibility of its ceasing to exist. Everybody knows that his indefatigable labors have done vastly much to keep it alive. The indications of decay, it is said, are more especially seen in the formation of so many new societies, semi-national in character, and in the fact that large numbers of distinguished physicians and surgeons stand aloof, and do not participate in its annual meetings as in the past years.

In short, they assume that the Association is not regarded, nowadays, as indispensable for the unification of medical interests as formerly. Its associations are agreeable enough, it is said, but that it is no longer the centre of centripetal and centrifugal forces for the maintenance of our medical system; that were it not for the opportunities it affords for cheap travel to our great cities, the recreation, and the entertainments, which give variety to pleasurable journeys, it would soon go to pieces.

There is no thoughtful man, I think, who could regard the suspension of these annual meetings in any other light than as a public and professional calamity. What the Association has done for the elevation and unification of the profession, I have no space to recount; moreover, I believe that its power to do good could never have been exerted to a greater purpose than at this time. It has required many years to formulate all the methods for its government and higher work. It can and must be made so powerful in promoting a broader and more scientific scholarship, that the fraternity shall, at length, gain the public estimation as the most highly educated and trustworthy class of citizens of the Republic. It must command so much professional regard that every member of the fraternity shall give it his profound reverence, and consider it one of his highest titles to distinction to be a corporate fellow.

With higher culture of professional *esprit de corps*, and sustained by a powerful organ, there can be no aspersion by, nor combination of sectarian or irregular practice, nor any display of self-importance by individuals, or groups of regular physicians who hold themselves apart in haughty satiety, that can restrain the fulfillment of the beneficent aims of the American Medical Association.

If its great purpose can be accomplished in Chicago, let it remain; but I repeat, the consciousness of Chicago is so immensely inferior to that of our political capital, that I hope that all of us may see that the great destiny of the Association may more surely be accomplished at Washington.

CORNELIUS G. CONEGYS, M.D.

Cincinnati, Feb. 20, 1891.

To the Editor:—THE JOURNAL, has the most favorable geographical and business location that could be found in the United States. THE JOURNAL has been a success from the very beginning, and has a history of which its friends may well be proud. It has appeared regularly, and its pages have always been filled with

matter that deserves to be read by every progressive physician. The editorials compare well with those of any medical journal published in the East.

I am satisfied that if the future location of THE JOURNAL would be left to a vote of every member of the American Medical Association as it should be, nine out of every ten votes would be cast for Chicago.

If our brethren in the East wish to make THE JOURNAL what every member and the Supervising Editor wants it to be, let them contribute scientific articles for its columns, which will be eagerly read and thoroughly appreciated by every member of the Association, instead of wasting time and talent in criticising the present management.

N. SENN.

Milwaukee, March 4, 1891.

To the Editor:—It was resolved, at a recent meeting of this Board, that it is the desire of this College that the place of publication of THE JOURNAL remain in Chicago.

W. F. MILROY,

Secretary Board Trustees,

Omaha Medical College.

Omaha, Neb., March 4, 1891.

To the Editor:—I think that Chicago is much the better place for the publication of THE JOURNAL, it being the most central and most convenient place. I have written to the different members of the Board of Trustees, expressing my views on the subject.

The membership of the American Medical Association is made up largely of physicians who live in the West and South; the most active work in the Association is done by members who live in the territory tributary to Chicago, and I am quite certain it will be found that a vast majority of the members of the American Medical Association wish to have THE JOURNAL published in the future, as it has been in the past, in the city of Chicago, and would look with jealous eyes upon any attempt to remove it elsewhere. They will certainly most bitterly oppose any attempt to remove it farther East.

St. Paul, Minn., March 2, 1891.

JOHN F. FULTON, M.D.

To the Editor:—The American Medical Association may now be considered a success. THE JOURNAL, published where it has been, in Chicago, and edited as it has been, has contributed more to accomplish this end than any other and all other influences combined. Believing this as strongly as I do, I say let it alone! All things that are doing well should be let alone. Chicago is nearer the home of the great number who contribute to the make-up and support of the Association than New York, Philadelphia, or Washington City would be. Men will support home matters better than they will more distant ones.

Dr. N. S. Davis, of Chicago, has done more to make the Association a success than any other man. Why should he be thus insulted and his home despised? I for one am opposed to this high-handed outrage.

ROBERT CRAWFORD, M.D.

Cooperstown, Pa., March 3, 1891.

To the Editor:—Deeply interested in every move likely to contribute to the enhancement of material and scientific interests of THE JOURNAL, we regard as the exponent of the best literary and scientific culture of the first, best and largest medical organization of our country, I cannot but enter my personal protest against the removal of the "plant" and editorial management of THE JOURNAL from Chicago to Washington, D. C. Certainly no man of broad scholarship, literary and scientific culture, can find one incontrovertible argument in favor of the contemplated change. In every element of material

advantage, and facilities for ready and quick distribution, no city in our country, when we regard THE JOURNAL'S constituency, is comparable to Chicago. And I feel assured no man will have the temerity to deny us such a measure of classical, special and general scholarship as render secure the best educational interests of this representative journal? Central, ambitious, progressive, our city furnishes all the splendid environments calculated to inspire the best editorial management. I vote for Chicago!

WILLIAM T. AKINS, M.D.

Chicago, March 7, 1891.

To the Editor:—It is my opinion to the best interests of THE JOURNAL to have it remain in Chicago. The geographical location of Chicago is superior to Washington or any other city. It being the great commercial centre of the Northwest, and a centre for medical education. Hence it would not be advantageous to the interests of the Association, and a detriment to the financial interest of THE JOURNAL, depriving it from a large legitimate advertising patronage, a factor in support of THE JOURNAL.

The editorial department has been well managed and gives, I believe, general satisfaction to the majority of the members of the Association. It would be wise to let well enough alone.

THOS. W. FORSHEE, M.D.

Madison, Ind., February 26, 1891.

To the Editor:—I am in favor of keeping THE JOURNAL where it now is.

B. F. ROLFE, M.D.

Staceyville, Ia., March 6, 1891.

MISCELLANY.

DR. HOMER ALLEN JOHNSON.—At a recent meeting of the Council of the Northwestern University it was

Resolved: That by the death of Homer Allen Johnson, A.M., M.D., LL.D., the Northwestern University has lost one of the most active and efficient founders and supporters of its medical department, an active and wise member of its Board of Trustees and Council, and an influential patron and friend of all its interests, the medical profession one of its most learned, skillful and honorable members; the city and state one of its most enlightened, patriotic and useful citizens, the cause of education and sanitary science one of their most earnest supporters; and his family one of the most unselfish and affectionate of husbands and fathers.

Resolved: That the foregoing be entered upon the records of this Council, and a copy of the same transmitted by the Secretary to the family of the deceased, and a copy furnished for publication in the medical journals.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from March 1, 1891, to March 6, 1891.

Major Samuel Horton, Surgeon, is granted leave of absence for two months, on surgeon's certificate of disability. By direction of the Secretary of War. Par. 7, S. O. 49, A. G. O., Washington, February 1, 1891.
Capt. William O. Owen, Jr., Asst. Surgeon, is relieved from further duty in the Dept. of the Missouri, and will report in person to the commanding officer, Jefferson Bks., Mo., for duty at that station, and by letter to the Superintendent of the recruiting service, by direction of the Secretary of War. Par. 2, S. O. 44, A. G. O., Washington, February 26, 1891.
The following named officers, having been found by Army Retiring Boards incapacitated for active service on account of disability incident to the service, are, by direction of the President, retired from active service at this date, under the provisions of Section 1251, Revised Statutes. Capt. J. Victor De Haune, Asst. Surgeon, and Capt. William R. Steinmetz, Asst. Surgeon. Par. 18, S. O. 44, A. G. O., February 25, 1891.
Major Henry M. Cronkhite, Surgeon, will report in person to the commanding officer, Ft. Adams, R. I., for temporary duty at that post, until the arrival of a successor to Major Samuel M. Horton, Surgeon, when he will return to his proper station. By direction of the Secretary of War. Par. 5, S. O. 45, A. G. O., Washington, February 27, 1891.
Capt. Frederick W. Elbrex, Asst. Surgeon, having been examined by a board of officers and found physically disqualified for the duties of a surgeon with the rank of Major, by reason of disability incident to the service, is, by direction of the President, retired from active service with the rank of Major, under the provisions of the Act of Congress approved October 1, 1890, to date from February 21, 1891, the date from which he would have been promoted to the grade, by reason of seniority, it found qualified. Par. 1, S. O. 45, A. G. O., February 27, 1891.
The following named officers, having been found by Army Retiring Boards incapacitated for active service, on account of disability incident to the service, are, by direction of the President, retired from active service at this date, under the provisions of Section 1251, Revised Statutes. Major William S. Tremaine, Surgeon, Major Leonard W. Loring, Surgeon. Par. 19, S. O. 45, A. G. O., Washington, February 27, 1891.
Capt. William B. Davis, Asst. Surgeon, is granted leave of absence, since granted in S. O. 22, Div. of the Atlantic, February 5, 1891, and further extended one month, by direction of the Secretary of War. Par. 5, S. O. 45, A. G. O., Washington, February 28, 1891.
Major Henry Lippincott, Surgeon, is relieved from duty at Ft. Union, N. M., to take effect upon the final abandonment of that post, and will then proceed to Ft. Adams, R. I., and report in person to the commanding officer of that post for duty as Post Surgeon, reporting by letter to the commanding General, Div. of the Atlantic. By direction of the Secretary of War. Par. 9, S. O. 45, A. G. O., Washington, February 28, 1891.

ECTOPIC PREGNANCY; WITH PRESEN-
TATION OF SPECIMEN.

Read before the St. Louis Medical Society, November 14, 1890.

BY YOUNG H. BOND, M.D.,

OF ST. LOUIS, MO.

PROFESSOR OF GYNECOLOGY, MARION-SIMS COLLEGE OF MEDICINE;
ATTENDING GYNECOLOGIST TO THE GRANT AVENUE FREE
DISPENSARY; CONSULTING GYNECOLOGIST TO THE
ST. LOUIS FEMALE HOSPITAL AND ST. LOUIS
CITY HOSPITAL.

I do not wish to report a case of mere ectopic pregnancy, since I did not see the patient from whom this specimen was obtained. She bled to death and presented the usual symptoms incident to a lesion of this character; the diagnosis was not made.

On post-mortem the abdominal cavity was found filled with clotted blood, which had proceeded from a rupture of the right Fallopian tube.

With great confidence, I pronounce this a case of ruptured tubal pregnancy; for whilst no fetus was found (none being sought for), the gross appearance of the parts justifies the exclusion of all other lesions to which the tubes are liable. Nothing is found to sustain the belief that the inflammatory disturbances to which the tubes are liable, or the neoplasms which, in rare instances, attack them, produced the pathological appearances present. Extravasation of blood into the tubes, with subsequent rupture into the abdominal cavity, in consequence of distension, unassociated with extensive inflammatory alterations of the walls of the tube, rarely, if ever, occur; therefore, there is no question but that the specimen is that of a ruptured tubal pregnancy. It will be submitted to Prof. Summa for microscopic examination, and there is no doubt that histological appearances will be found that will demonstrate the existence of placental tissue at the point of rupture, and that the uterine cavity is lined with a membrane approaching in character decidua vera. We have here the uterus, together with both broad ligaments and ovaries. The uterus is three times as large as the normal unimpregnated uterus, and from its size we may predict there will be found evidences of chronic metritis, associated with an increased development of the mus-

cular element, the latter being incident to the innervation of pregnancy.

The uterus is much larger than is usually the case at the stage of extra uterine pregnancy reached in this instance, which is perhaps six weeks. The ovaries, too, are quite large. No evidences of a corpus luteum of pregnancy can be detected. Small cicatrices can be seen, the sequelae, perhaps, of ruptured follicles, but nothing pathognomonic of a corpus luteum of pregnancy.

In 1881 Mr. Tait stated that evidence was rapidly accumulating in his hands that "corpora lutea are not a necessary result of the maturation and shedding of true ova;" and in 1889 he reiterates the same assertion. The determination of the truth in this regard may possess an important medico-legal bearing, and no case that may come before us that can throw light upon this subject should escape scrutiny. Perusal of nine-tenths of all that has been written upon the subject of ectopic pregnancy will impress one with the belief that ectopic gestation is a veritable curiosity—a case of nature let loose, without restraining or guiding influences, that should act with any degree of uniformity in determining the steps of her aberrant course. And as a consequence, it was for a long time thought to be idle to attempt to establish anything like a defined line of action, in dealing with a process so eccentric. Thus is explained the fact that century after century rolled on, and no intelligent method of combating the deadly agency of this process was discovered. Countless thousands of women have gone to their graves prematurely, because no Tait had arisen to unravel the mysteries of ectopic gestation, and point out a sure and reliable method of dealing with the same.

Although the propriety of performing laparotomy, tying off the vessels, and removing the gestation-sac, had been by many suggested, it was not until 1853 that one appeared who had sufficient courage and conviction upon the subject to put his conception into actual practice. In 1873 Tait formulated certain conclusions respecting ectopic pregnancy, and so far as has come to my knowledge, all carefully conducted observations upon the subject since then have served to establish their correctness.

He claims that all ectopic pregnancies are pri-

marily tubal, unless, perchance, there should be an ovarian variety, which, as yet, has not been proved. Clinically, two kinds of tubal pregnancy are met with, viz.: the one occurring in the free portion of the tube, and the other in that portion of the tube embraced in uterine tissue, the old interstitial form.

In explaining the cause of Fallopian pregnancy, he refers to the similar states found in the mucous surface of the uterus after menstruation, and that of the tubes in desquamative salpingitis.

Menstruation is regarded as a nidation process, a state in which the epithelial layer of the mucous membrane of the uterus has been thrown off, thus fitting the cavity for the retention and nutrition of the fecundated ovum during the period of its early existence, and for the formation of the placenta subsequently.

The cilia of the healthy tube, acting toward the uterus, assist in conducting the ovum to the uterine cavity, and at the same time hinder the ingress of spermatazoa.

A result of desquamative salpingitis is to remove the cilia and place the mucous surface in a vascular state similar to that of the uterus after menstruation, as regards its power to furnish nutrition to the ovum in its early life. Parenthetically I will state that the conditions for the formation of the placenta are not limited to uterine tissue, even though the Fallopian tubes be regarded as a part of the uterus.

When we reflect that the placenta is a product of the chorion, and that the latter is the property of the ovum, we can understand how the inherent forces of the fecundated ovum will take on activity, if the requisite warmth, moisture, and nutritive elements are at hand, as has been evidenced by the implantation and growth of fertilized ova along fistulous tracts following hysterectomy.

In confirmation of the desquamative theory, Parry says "women who have become pregnant outside of the uterine cavity often show a previous inaptitude for conception, the interval between marriage and the first impregnation being frequently very long.

If the woman has borne children, a period of sterility frequently precedes the extra-uterine pregnancy. The fact that the woman has been sterile points to the conclusion that there has been Fallopian trouble. The recent observations of Formas, read at the meeting of the American Association of Obstetricians and Gynecologists, serve to confirm the theory of Tait as to the influence of desquamative salpingitis in occasioning extra-uterine pregnancy.

If it be conceded that impregnation usually takes place in the tube, we thence derive an argument against the theory that desquamative salpingitis plays an important rôle in causing Fallopian pregnancy. It will be remembered that in the latter part of the last century and the early

part of this, it was believed that the spermatazoa passed along the Fallopian tube, reached the ovum and conception took place at the ovary, and that the impregnated ovum retraced its steps and entered the cavity of the uterus.

Experiments on lower mammals show that the spermatazoa are usually found high up in the cornua of the bi-partite uteri (the cornua erroneously supposed to be Fallopian tubes). Fallopian tubes only exist in the higher order of animals, those that have assumed the upright posture. That is the position advanced by Mr. Tait.

The observations of Parry and Formas as regards the association of sterility and extra-uterine pregnancy, will find general confirmation. The very first case of extra-uterine pregnancy of which we have any history was furnished in 1594, when a Dr. Primrose operated successfully. That case was preceded by the occurrence of extra-uterine pregnancy, a dead child having been removed several years before through a large aperture in the abdominal parietes in consequence of necrosis of the part.

An ovarian pregnancy may possibly occur, but it has not been conclusively shown. In consonance with the view that pregnancy occurred at the ovary, it was formerly believed that most cases of extra-uterine pregnancy were really cases of ovarian pregnancy.

Many pathological specimens are found in museums labeled "ovarian pregnancies," and the appearances furnished by a Fallopian pregnancy when the gestation-sac has not been ruptured, are very suggestive of an ovarian form. But a close examination of these specimens serves to demonstrate that very few, if any, are ovarian pregnancies. Possibly some of them are ovarian in part, and that we might expect; we have cysts involving the fimbriated portion of the Fallopian tube and the ovary; both structures playing a part in their formation; and it is reasonable to suppose that in certain instances the fimbriated extremity of the Fallopian tube, in consequence of inflammatory action, would become adherent to the ovary, and the spermatazoa be carried down to the ovary, and impregnation there take place. In that case we would have a combined form of ovarian and Fallopian pregnancy. In one portion of the gestation sac we would have ovarian tissue and in the other the tissue of the Fallopian tube. In order to prove that any case is strictly one of ovarian pregnancy, it would be necessary that the Fallopian tube should be intact (normal), the uterus should be intact, and at least one ovary thoroughly intact; and whilst the other ovary might not be present, to demonstrate conclusively that it was an ovarian pregnancy, ovarian stroma should be found throughout the cyst wall of the pregnancy. I do not know a single case recorded in which ovarian tissue had been found throughout the cyst wall.

Tubal Form of Pregnancy.—Mr. Tait claims that all ectopic pregnancies are primarily tubal, taking place in the free or interstitial portion of the tube. It is only exceptionally the case that impregnation takes place in the uterine portion of the tube. When, however, tubal pregnancy occurs the fecundated ovum will be accommodated in the Fallopian tube only for a short time; the tube will be ruptured at some time before the expiration of the fourteenth week. If the rupture occurs at the upper portion of the tube where the layers of the broad ligament fall over it as a curtain, the opening will be into the peritoneal cavity; and we will have as a result death from hæmorrhage or septic peritonitis. In the vast majority of cases death very promptly ensues, usually in time ranging from a few hours to a few days. The patient may die from hæmorrhage in its primary stage—there being no interruption to the hæmorrhage from the first to the last. It may be stayed for a time by a clot, and then recur. As a rule, death ensues from primary hæmorrhage, since there are no influences to arrest it. The parts being exceedingly vascular at the point where the hæmorrhage occurs a large quantity of blood is poured into the peritoneal cavity. By its presence peristalsis is excited; the patient in consequence of her suffering is restless; cannot be kept still; therefore, the conditions requisite to the coagulation of the blood cannot be complied with.

When rupture occurs at the lower portion of the tube, we have a sub-peritoneal pregnancy, and there ensues one of five results:

1. The fetus may live and reach a viable period.
2. It may be converted into a lithopædion.
3. It may perish and be absorbed as a hæmatoma.
4. It may undergo suppuration and may be discharged through the bowel, vagina, the bladder or abdominal wall at or near the umbilicus.
5. It may develop up to a certain point and then rupture into the peritoneal cavity, constituting what is known and designated as a secondary rupture. This secondary rupture may cause death, or the fetus may be extruded into the abdominal cavity without amnion, chorion or decidua to invest it. Cases are reported in which the fetus has been found in the abdominal cavity, surrounded by the intestines, with no proper covering at all; but in such instances the placenta was found in general attached sub-peritoneally, and the presumption is strong that the pregnancy had proceeded up to perhaps the seventh or eighth month, and then a portion of the broad ligament had given way, and the fetus was emptied into the free peritoneal cavity. This assumption is supported by the fact that the peritoneal secretion exercises a decided digestive influence upon soft structures such as obtain during the early life of the embryo.

Nor is the rupture of the Fallopian tube due to distension. At the point where the placenta happens to grow, if from the upper wall of the tube, it will penetrate the true tissue of the tube in the form of venous channels, the tubal tissue becoming constantly thinner; a rupture will finally take place as a consequence, and then, of necessity, an alarming hæmorrhage occurs.

If the placenta should be developed at the lower portion of the tube, in the direction of the space between the broad ligament, a rupture will take place by the same processes, in that direction, and then are presented either of the five conditions enumerated.

Diagnosis.—It surely is a decided desideratum to be able to diagnose extra-uterine pregnancy—tubal pregnancy before rupture. Were we thus endowed, and the proper course pursued, many lives would be saved. Should the patient consult us about her condition previous to the time of rupture, and we be induced to make a physical examination, I should think the testimony of physical signs considered in connection with the subjective symptoms, in the vast majority of cases, would amply justify the presumption of extra-uterine pregnancy; in fact, a presumption so strong that the neglect to make an exploratory laparotomy would be inexcusable. Suppose a case: A woman gives the history of sterility, a condition not the consequence of her choice; has been regular in her menstruation, and yet a few weeks previously she had missed a menstrual period; had passed a week, ten days or two weeks or more; then menstruation returned, profuse and irregular; she had pain in the region of the Fallopian tube; her attention is directed to that region by the sense of discomfort, and recurring attacks of pain; her breasts are enlarged; suffers from nausea; and may or may not present those subjective indications of pregnancy that exist when the pregnancy occurs in the uterus.

The cervix is soft, and the uterus continues to develop up to about the first or second month; and in addition, we have in the region of the Fallopian tube, upon the side of the uterus or posteriorly to it, a mass of appropriate size and form to that of a pregnancy at the particular period. This combination of symptoms would furnish strong presumptive evidence of pregnancy; if, however, after one examination had been made and the size of the mass definitely ascertained, a subsequent examination should reveal a proper increase in size, then the conclusion would be almost inevitable. In a case of hydro-salpinx the outline of the tumor, in a case of pyo-salpinx, the increased sensibility will assist in reaching a satisfactory conclusion. Diagnosis of tubal pregnancy, before rupture, have been made, and appropriate operations performed; and when this sequence of symptoms is present our minds should be on the *qui vive* for the possibility of such a

condition of things. The diagnosis of tubal pregnancy at the time of rupture is almost unequivocal; no excuse could hardly ever be claimed for failing to diagnose it, and to invoke promptly the one only surgical interposition that can rescue from impending death. The woman, as a rule, is taken suddenly ill; complains of pain in the pelvic region; at once becomes collapsed; is faint; is almost pulseless; cries for water, the demand being like that of the wounded soldier when profusely bleeding; her anæmic state indicates conclusively that she is suffering from loss of blood, and if there is no palpable explanation for it elsewhere, it is imperative that her surgeon open the abdomen and ascertain that she is not bleeding from a ruptured Fallopian tube.

In respect to a diagnosis of a rupture of the tube into the broad ligament, the subjective symptoms render less assistance than in the case of rupture into the abdominal cavity, but the physical indications are more positive. The woman suffers from collapse to a degree corresponding to the amount of blood effused. In some it is very great; even to the separation of the broad ligament and the formation of a virtual stricture around the rectum, and thus obstructing the passage of the feces. In such cases the degree of systemic disturbance is very pronounced. If the symptomatic history of extra-uterine pregnancy be present together with the sudden occurrence of collapse, and the finger introduced into the vagina detects a hæmatoma, of concave form below, and sufficiently large to reach the pelvic inlet, being convex above, the conclusion is almost absolute that the case is one of tubal pregnancy ruptured into the broad ligament. If the rupture has thus taken place, and the child continues to live, it will be impossible to diagnose the existence of a living child until after the expiration of the fourth month. After this period the heart sound and souffle will afford sufficient data to determine the existence of a living child. In case of the death of the child, at or near full term, there usually precedes a process of spurious labor. Women sometimes are in labor for several days, exhibit symptoms that simulate those of true labor, but the cervix is not drawn out as it is in normal pregnancy at the full period. After the cessation of labor pains the mass promptly becomes reduced in size, the amniotic fluid undergoes absorption, the amnion closely invests the child, and the process of digestion rapidly goes on. Prompt reduction in the size of the abdomen in connection with the absence of motion is one of the strongest evidences that an extra-uterine fetus has perished.

Interstitial Pregnancy.—It is impossible to diagnose this condition either by physical or subjective symptoms on account of the many and conflicting conditions that exist. These cases usually rupture into the peritoneal cavity at a

time varying from three to twenty weeks. If it were possible to diagnosticate a case of interstitial pregnancy, one mode of treatment only would be indicated, viz., Porro's operation, removal of uterus and child.

Treatment.—Primary rupture into the abdominal cavity demands laparotomy promptly; that portion of the broad ligament in which the sac is situated must be ligated and removed. The result in such cases is usually a very happy one. Mr. Tait reports thirty-eight cases with only one death; Martin reports eleven cases with three deaths; others report favorable results; therefore, in view of the fearful mortality that obtained previous to the institution of this method of treatment, there no longer exists any question as to the propriety of this procedure.

In Case of Rupture into the Blood Ligature.—If the fetus perishes at the time of rupture, a hæmatoma is formed; if the hæmatoma be moderate in size the question arises, shall it be removed surgically or shall it be left with the hope that it will disappear by absorption. Some contend that an operation is the proper thing; others deny that laparotomy and the opening of the broad ligament and cleaning out the collection of blood is the best course. If the condition of the patient seems not to be serious, and the collection of blood not unduly large, I would be disposed to leave it to be absorbed; for hæmatomata are not of very uncommon occurrence, and it is known that they generally undergo absorption.

As a rule, therefore, no operative measure is called for, as this mass of blood will be absorbed. It has been contended, however, that in all cases of hæmatoma complicated with extra-uterine pregnancy, that removal by abdominal section or an operation on the broad ligament through the vagina should be practiced for the reason that in such cases sepsis sooner or later attacks the effused blood, upon the assumption that the desquamative salpingitis was due to a septic condition, and that the septic germs still existing in the Fallopian tube would, in the course of six months or more, infect the blood poured out into the broad ligament. As a matter of course, if the discharge of blood into the broad ligament was of such extent as to endanger the life of the patient or render it almost certain that suppuration would ensue, the wise course would be to perform laparotomy, open the broad ligament, cleanse it thoroughly, and if necessary use some styptic application and stitch the divided portion of the broad ligament to the abdominal opening, and if necessary insert a drainage tube.

What line of action shall be adopted when extra-uterine pregnancy is diagnosed at the fourth month or thereafter, the fetus being alive but not viable? Shall efforts be made to destroy the child by electricity, by the injection of morphia or by other means, or shall we by a laparotomy

remove it at once, or wait till it reaches a viable period and then attempt to save both mother and child?

When such a case is diagnosed as early as the fourth month, or soon thereafter, an attempt at its removal should be made, otherwise the interests of the mother will be compromised in a degree commensurate with the delay up to the viable period or beyond, for the smaller the placenta the less the danger; the greater also the possibility of tying off the vessels and greater likelihood of saving the mother. But if the child be near the viable period I should wait until it reached the full period.

Martin, of Chicago, has recently experimented with the view of determining the comparative potency of the faradic current and galvanic current in destroying eggs in the process of incubation, and has awarded it to the latter.

In regard to the destruction of the child, statistics show that in 1888 and 1889 eleven cases were operated on in which the children were viable; four mothers died, and four children were saved, making a mortality of 36 per cent. In operations performed from six to eight weeks after the death of the foetus, of forty-four cases reported in 1888 and 1889, there were nine deaths, a mortality of 20 per cent.

These are vastly more favorable results than were obtained in the time of Parry, who says in 1873, "of nine women operated on during fetal life, or soon after its extinction, they all died." Then the clamp was in use, and no antiseptic precautions were employed. Consequently, causes of mortality prevailed that do not exist at the present day.

Operation of Laparotomy, Removal of the Living Child.—Mr. Tait recommends that the umbilical cord be tied close to the placenta and that the latter be left intact. The abdominal incision should be made not in the median line, the conception being below the broad ligament, as the gestation sac increases in size the broad ligament is carried up; consequently, the incision is made to the right or to the left of the median line, as the case may require; if the child is upon the right side the incision should be to the right of the median line, and *vice versa*. By that means it is sought to avoid entering the peritoneal cavity at all. The sac, after thorough ablation, atmospheric air being displaced by hot water forcibly injected and gradually abstracted, is sewed to the opening in the abdominal wall, hermetic closure being attempted.

Efforts have been made to remove the viable child through the vagina, but the results have been unfortunate. I am acquainted with but one case in which a living child has been thus removed. The circulation under such circumstances is so seriously interfered with that the child perishes before delivery is accomplished; lapar-

otomy, therefore, furnishes a much more promising mode of operation, in these cases, than extraction per vaginam.

If the child, however, has developed in the broad ligament, and a rupture, with hæmorrhage, has taken place secondarily from the broad ligament into the peritoneal cavity, and the symptoms are sufficiently grave, then it will be imperative that we open the abdomen, ligate the vessels below the placenta, if possible, and remove the extraneous parts.

In case of suppurating ovum, the mass not being large, and it being possible to reach it readily from the vagina, its removal in that direction is advised; but if the mass be large and there be complicating conditions resulting from inflammatory states, laparotomy and removal of the suppurating contents is the proper procedure. The cyst wall should be sewed to the opening in the abdominal parietes and drainage practiced. Ten cases have been reported in which, after recovery from one extra uterine pregnancy, a like pregnancy occurred upon the other side.

The question very naturally presents itself whether or not, in such cases, the removal of the appendages of both sides is indicated. Salpingitis is bilateral in nearly one-half of the cases, a significant fact in this connection.

Grand and Page Aves.

SOME COMMON ERRORS IN DIAGNOSING DISEASES OF THE SKIN.

Read before the Chicago Medical Society, February 1, 1891.

BY JOSEPH ZEISLER, M.D.,

PROFESSOR OF SKIN AND VENEREAL DISEASES IN THE CHICAGO MEDICAL COLLEGE; WOMEN'S MEDICAL COLLEGE, POST-GRADUATE MEDICAL SCHOOL, DERMATOLOGIST TO COOK COUNTY HOSPITAL, MEMBER OF THE AMERICAN DERMATOLOGICAL ASSOCIATION, ETC., ETC.

There is surely no other class of diseases in which the chief symptoms are more tangible and conspicuous, more ready for close inspection and touch, more easy of examination by the eye, be it unaided or armed with loupe and microscope, than in affections of the skin. And yet perhaps in no other branch of medicine are diagnostic errors committed with equal frequency. The cause for this peculiar discrepancy lies partly in the fact that real difficulties are indeed but too often encountered, inasmuch as diseases of essentially different etiology and nature may assume similar pictures. Under such circumstances only large experience and often only a continued observation of the course of the disease will help in arriving at a correct understanding of the case. In a large number of instances, however, the symptoms are so clear and unmistakable that a misinterpretation of the same, by the majority of general practitioners, appears in an entirely different light; and without wishing to do anyone particu-

lar injustice, I may state it as my experience that many physicians, who in every other direction are splendidly equipped, look upon dermatology as a *terra incognita*, and are usually free in admitting their inability of recognizing even common forms of cutaneous disorders. This may well be excused, if we consider the entire lack of facilities, at least in our city, for the study of this important branch of medicine, and more especially the curious fact that, with the many and well-appointed hospitals in our city, there is not one single ward set aside for the treatment and methodical study of skin and venereal diseases. To show how different the opportunities in other cities are, I may mention that Vienna, with no more inhabitants than Chicago, has in the General Hospital three distinct services for cutaneous and syphilitic affections, with an aggregate of about 300 beds, besides largely attended out door departments, and that four other military and civil hospitals have each a special dermatological service, with several wards, a chief and his assistants. This subject has been dwelt upon with great emphasis by Dr. P. A. Morrow, in an address recently delivered before the American Dermatological Association.

Returning, after this deviation, to my theme, let me say first, that a frequent source of error in diagnosing skin diseases is too great a reliance upon the statements of most patients. Time and again I have learned to appreciate the golden rule of my teacher, Kaposi, never to ask any questions of the patient, but to examine his skin objectively and uninfluenced, and, so to say, to read on his skin all the anamnestic data. Duration of the trouble, presence or absence of itching, previous treatment and other valuable points will thus be often easily learned without the aid of the patient, which will greatly contribute to make him feel that his case is well understood. How easily patients may intentionally or involuntarily mislead the physician I experienced in a very striking manner only a few days ago. A young man came to see me for what he believed to be quinsy sore throat, of which he had suffered for the past two weeks. Looking into his mouth and throat, I immediately informed the patient that he had syphilis and asked him how long ago he had had a chancre. He vigorously denied any such accident and thought it impossible that he could have been infected. I demonstrated to him the presence of numerous mucous patches on his tongue and tonsils, the corners of his mouth, and even the depressed cicatrix on the left border of the tongue, in all probability the seat of the primary lesion, but all this did not seem to him convincing enough. I then made him undress and discovered on his chest and back and the upper arms, a classical roseola, and found all the superficial lymphatic glands distinctly enlarged. This at least settled the diagnosis,

although it did not clear up the mode of infection. However, we cannot be expected to play the part of detective always.

This case of an unconscious infection by the syphilitic poison is by no means a unique one, and I could cite from my own observations a number of similar occurrences. We can learn another lesson from it, namely, to examine, whenever practical, the whole integument, and not only the place which is offered for inspection. I have still under treatment a young druggist, who some time ago was treated by one of his medical friends for what appeared to be a very rebellious acne of the face. When he first consulted me I noticed, besides the eruption on his face, a well developed iritis of the left eye. Suspecting the specific nature and causal connection of both affections, I examined his body, which I found literally covered with a large papular syphilide. The young man, who evidently had not paid much attention to his extensive eruption, was perfectly alarmed to learn the nature of his trouble and, protesting his innocence, assured me that for the past year he had not indulged in sexual intercourse, as he expected to get married to a young lady. A thorough search revealed the cicatrix of the former initial lesion near the tip of the tongue, and I learned that this place had for some time been the seat of a stubborn sore. The young lady in turn proved also perfectly innocent, for an examination showed her to be a virgo intacta, adorned, however, by some condylomata lata and mucous patches in the mouth, for which she had to thank her own father, who in an intoxicated condition had attempted to abuse her.

This acquisition of syphilis as a non-venereal disease, when no history of infection can be gained, is too often overlooked. I shall never forget the case of a busy fellow practitioner in this city, who for some time had noticed an eruption on his body and the palms of his hands, which he showed to several professional friends, who in the absence of any anamnestic data, never suspected syphilis; while one of them considered the case as eczema and prescribed diachylon ointment, the next pronounced the eruption as psoriasis and recommended chrysarobin, until the persistence of the symptoms and the complication by iritis at last put him on his guard.

While we thus see how grave errors may sometimes be committed by overlooking the syphilitic nature of cutaneous manifestations, the opposite mistake of pronouncing as specific an eruption of entirely different nature is probably made just as frequently. Once a prominent lawyer visited me with his wife, and desired my opinion about a breaking out on the lady's body, which, by the family physician, had been declared as syphilitic. I found a large number of pea-sized pale red papules, covered with glistening, silverish white scales, which could easily be removed, when a

minute bleeding point would be noticed; very little itching, no glandular infiltration, no alopecia, no sore throat, in short a case of psoriasis, which by its somewhat acute development, deviated from the ordinary type. But even chronic, typical cases of psoriasis, with large, characteristic scaly patches are often taken as signs of syphilis, treated by mercury and the iodides, and sent to the Hot Springs.

Last year I was called to one of the hospitals to see a young girl with extensive ulcerations and hemorrhagic bullæ of the skin, which the house physician had treated for some time with antispasmodic remedies. I called the attention of the young Esculap to the bleeding of the gums and nostrils, to the irregular shape, the soft edges, the hemorrhagic base of the ulcers, and still further referred him to the hospital record, which showed that the patient had previously been treated there for a similar attack, which then was diagnosed by me as purpura hemorrhagica, or Werlhoff's disease. The child was then, partly on account of the improper treatment, in a very miserable condition, and died soon afterwards.

Acne varioliformis, that peculiar pustular affection, which has been described under various designations as acne frontalis, a. necrotica, a. atrophica (Bulkley), molluscum sebaceum (Bazin), is also occasionally regarded as a specific trouble, perhaps because cicatrization terminates the process. This disease is somewhat rare, but the peculiar localization, mostly on the forehead and anterior part of the scalp, occasionally on the nose and in the bearded face, less often on the back, the formation of thick crusts after the pustules have desiccated, the resulting depressed scar, the recurrence of the eruption in irregular intervals will help to strengthen the diagnosis.

As just indicated, a frequent source of error in recognizing skin diseases is indeed a lack of acquaintance with their peculiar localization, which is sometimes the only important factor in determining the diagnosis. Scabies *f. i.* is always found on certain well defined places of predilection and leaves the face, with rare exceptions, free. And yet, incredible as it may sound, I recently had a patient, who for five months had been treated for that trouble under differing diagnosis, as urticaria, eczema, and even lichen, although the penis and buttocks, and interdigital spaces were almost labeled with the characteristic burrows.

Prurigo, also, can only be recognized by examining the whole integument, when the extensor surfaces will be found principally involved, but the cubital, inguinal and popliteal spaces perfectly smooth. The existence of this disease in the United States was for a long time denied by dermatologists. But at the meeting of the American Dermatological Association in September, 1889, I was enabled to report a series of twelve

cases of prurigo, showing that this disease is by no means very rare here, and R. W. Taylor and James C. White have since confirmed my views, that prurigo is often overlooked and taken for eczema, urticaria, lichen, etc.

Another disease with a rather typical distribution of its lesions and which is frequently confounded with psoriasis, is eczema seborrhoicum, a very common type of eczema, as described in a classical manner by Unna. It occurs principally on the scalp, usually extending over the hair border towards the forehead and neck, on the eyebrows, external auditory channel, around the corners of the nose, on the sternal and interscapular surfaces and occasionally affects the axillary, suprapubic and genito-crural regions. The scales differ from those in psoriasis in that they are more fatty, scanty and never imbricated. I have no doubt that in many instances of claimed cures of psoriasis the real nature of the trouble has been that of a seborrhoical eczema, which by the gyrate outlines of some of the patches and its other features will sometimes simulate a light case of psoriasis.

The idea that most skin diseases are caused by systemic derangements, not to say by impurities of the blood, seems still to be quite prevalent, even among modern physicians, and thus sometimes near lying local causes will be overlooked, whose removal would easily accomplish a cure. An interesting illustration of this fact was sent by me in a very respectable young lady from California, who spent some time with relatives in Chicago, and soon after her arrival began to notice an urticarial rash on her body. The family doctor very promptly diagnosed hives and prescribed cathartics and alteratives, but new crops of wheals continued to appear. After being troubled some four weeks she came to consult me, and I modestly inquired about the young lady having noticed in her bed some six-legged companions. This was blushing confirmed, after which the treatment was suggested very easily. In another case a young man who had recently arrived here from New York, noticed an extensive eruption on the body, which had unsuccessfully been treated under the supposition, that it was an acute papular eczema. Diligently examining his body, which was covered with a luxuriant growth of hair, I succeeded to pick up with my tweezers from the base of a hair on the lower limb what appeared to be a little black point, but soon moved along slowly, as pediculi pubis will do.

During the late fall I see every year a number of cases of that well-defined dense, pruritus hiemalis—winter itch, which was first described by Duhring. This trouble does not seem to be universally appreciated and is frequently confounded with eczema. This word eczema is, by the way, of all dermatological terms, perhaps the

most abused, and there is hardly a skin affection to which I have not, on and off, found that name being given. All forms of pruritus, sycosis, lichen, prurigo and many parasitical dermatoses are occasionally baptized with the always ready name, eczema.

The term lupus, too, is often used in a very loose manner. First there is rarely a distinction made between lupus vulgaris, that one form of local tuberculosis of the skin and lupus erythematosus, which has nothing to do with the other and ought better to be called according to Hebra sen, *seborrhoea congestiva*. Then, the natural history of lupus vulgaris is often ignored. Thus I saw a short time ago that diagnosis made in a man near the fortieth year, who had a pea-sized follicular infiltration on his nose, while it is the rule for lupus never to appear after puberty. In another case a young man, over 30 years old, had an indurated and superficially ulcerated sore on his lower lip of the size of a hazel-nut. He came to me pretty well scared, for during six weeks of previous treatment two prominent physicians had pronounced it as epithelioma, while another took it for lupus. My first question of this patient, after examining the trouble was, "When have you had a chancre," to which the prompt reply was given, "Ten years ago." The presence of a large scar on the chin, the absence of any cartilaginous induration on the borders of the ulcer and the considerable pain further pointed to the diagnosis of an ulcerating gumma, which was sufficiently proven to be correct by the result of treatment, which in the course of ten days caused the ulcer to heal up.

I could easily mention, from my own experience, any number of further cases, illustrating various diagnostic errors, but this would go far beyond the scope of this merely suggestive essay. We all know that mistakes will sometimes be unavoidable, not only in dermatology, but in all other departments of medicine; as long, however, as the patient gets well, all is well. To show, on the other hand, how treatment based upon a false diagnosis may be followed by almost disastrous consequences, let me give you, in conclusion, a few notes about a case, which impressed itself especially strongly upon my mind. A young widow from Boston came to Chicago, upon the solicitation of her sister, to place herself under the care of a physician who stands at the front of the homeopathic fraternity. She suffered from extensive ulcerations in her face, particularly the nose, cheeks and lips. The doctor and his assistant, after reading up the case, decided upon the diagnosis, lupus, and finding in their reference works recommended as one of the methods of treatment, thorough scraping and excision, proceeded to follow this line of action. During a year the patient submitted to twelve different surgical operations under chloroform narcosis, but

new ulcerations appeared, and the continued suffering almost made her a physical wreck. When finally her remarkable confidence and power of endurance had given out, she consulted Dr. I. N. Danforth, of this city, who kindly referred her to me. I found on her face about half a dozen smaller and larger ulcers, which showed the very characteristic horse-shoe form. The greater part of the upper lip was missing, having been excised, which made the closing of the mouth almost impossible, and the whole ala nasi of the right side had also been sacrificed at one of those "surgical" procedures. Numerous disfiguring scars, moreover, gave the face a very pitiable aspect. The fact could easily be ascertained that the lady had, some years ago, been infected by her husband, which was followed by various eruptions on the body, and also by iritis. How, with such an anamnesis and with the unmistakable, objective signs, syphilis could be overlooked, and in entire defiance of all that is known about lupus, this diagnosis made, is beyond my comprehension. The lady made a splendid recovery as far as the ulcers then present were concerned, which healed in two weeks and never again appeared in a year; but whether a plastic operation, which she now contemplates, will be able to restore the shape of the nose and the mouth, when no flexible skin is available in the adjoining parts, I doubt very much. I have no further comment to make upon this case, except that I succeeded in preventing the lady from beginning a suit for malpractice.

Let me finally assure you that the foregoing paper is presented with no ill spirit, but with the sincere wish to awake a little more interest in the somewhat neglected study of dermatology.

MEDICO-LEGAL RELATIONS OF LAPAROTOMIES.

Read before the Chicago Medico-Legal Society, Dec. 6, 1899.

BY J. H. ETHERIDGE, M.D.,

PROFESSOR OF GYNECOLOGY, WEST MEDICAL COLLEGE,
CHICAGO, ETC.

Abdominal Surgery is comparatively new, there is nothing settled concerning the method of performing abdominal surgery, that is, *absolutely* and *definitely* as compared with what may be said to be settled about the treatment of fractures and dislocations. Whenever a case of medico-legal interest finds its way into the courts concerning the treatment of fracture or dislocation, there is very little difference of opinion in the minds of surgeons concerning the treatment of these cases—and they constitute nine-tenths of malpractice suits—for the reason that the treatment of fractures and dislocations is nearly as old as the human family. Abdominal surgery cannot boast of this ancient lineage, but is so recent and new,

and so many innovations are coming in every day that it seems to me one might, after looking over all the would-be settled points concerning the technique of the operation, conclude that there is nothing very definitely settled. And when the President of the Medico-Legal Society, in the seductive way he has, asks a man to handle this subject in ten minutes, before an audience of this kind, I think he has thrust a herculean task upon that man. I cannot thoroughly go over the wide ground covered by this subject in ten minutes, but I will touch briefly upon the most important points.

First, it seems to me we are attackable in many ways concerning the subject of positive knowledge in diagnosis. There is nothing that is more easy to be deceived in than the diagnosis in abdominal troubles. One can operate a hundred times in succession upon the various cases that come along in abdominal surgery, and make a correct diagnosis in perhaps sixty per cent, and in the others he may not, but when a man has operated ten, fifteen—twenty times, and has not made a correct diagnosis, he begins to feel like the surgeon who said, he who makes a diagnosis after he opens the abdomen is the man who is most cautious and correct. So I think if a doctor should be brought up before the courts to answer for a faulty diagnosis—for the doctor, legally, is responsible for his diagnosis—and is made responsible on that account, that he is possessed of a very large loophole of escape, in that so many doctors are unable to make a diagnosis before operating.

So many things are involved in abdominal surgery that have to be gone over clinically, that I cannot pause longer than to make the barest mention of these points:

First is the condition of the hands and sponges; the hands of the operator, the hands of the nurse, of the internes, and everybody implicated in the operation. It is a settled fact that complete cleanliness is the only thing permitted, any doubt as to this makes the doctor reprehensible. The most perfect means of cleansing the hands and sponges should be required of the physician.

A point was made in a recent case brought up in the East, concerning the length of time of an operation. It was claimed that the doctor was too long, and the astounding evidence was given by one laparotomist, that resection of the intestine ought not to occupy more than twenty minutes. That evidence was very material with the jury, since the physician had been some three and a half hours getting through with the operation. I think it is safe to say that no man can do that operation successfully and safely under two hours, and a man who goes upon the witness stand and gives such evidence as that quoted above is exceedingly dangerous, almost as dangerous as the man who testified that a case of

puerperal fever was owing to the uncleanness of the attending physician.

Next, as to the time of operating, whether before or after supervention of reaction. In all ordinary cases of gunshot injuries and the like about the limbs, surgeons, generally speaking, desire to await reaction before operating, but in cases of abdominal wounds, where intestines are perforated and fixed organs injured, we know that collapse almost always follows at once, and to await for reaction here would seem to me to be waiting for peritonitis to invade the premises and make short shrift of the patient. I think any one giving testimony and saying we ought to wait for reaction in such cases, is a dangerous person.

We all know that it is only a few years since gunshot wounds of the abdomen were first operated upon, but dogs have been shot, under anaesthesia, and the intestinal preparations closed up and the dogs have recovered and lived good long lives afterwards. In this investigation the intestines were distended by hydrogen gas for the purpose of locating the holes in the intestines that could not be located by ordinary digital examination. To-day there are some men in the country who believe that we are as bound to operate upon a man who is shot in the abdomen as we are to operate in almost any plain case in ordinary surgery. Statistics are hard things to combat: The old-fashioned treatment was to put the patient at rest, giving opium, and letting him run along in that way until the intestinal wounds healed and he escaped the possibility of fatal peritonitis; if he got well—well; if he didn't—ill; that was about all. Statistics in the State of New York, for the last ten years, compiled by skillful surgeons, show eighty-four cases of intestinal perforation by gun-shot wound operated upon with a mortality of eighty-three per cent. In the preceding ten years the number of cases treated, not by operation, resulted in a mortality of only thirty-five per cent. Therefore I think the man who goes on the witness stand and says this patient with an intestinal gun-shot wound should have been operated upon by the surgeon in attendance, that he should not have waited to take the old course, is very dangerous.

Now a few words concerning the incision: As a rule the incision should be as short as possible, still there are cases where the incision should be made from the pubes to the ensiform cartilage. So when a man says there is any cast iron rule in regard to the operation he doesn't know what he is talking about, and is giving misleading testimony.

Another point is concerning the pedicle, whether it be ovarian cyst or uterine fibroid. In years gone by, but not so very remote, the pedicle used to be treated with a clamp outside of the abdomen. Twenty years ago that was classical

treatment; to day it is not. It seems to be pretty well settled in the matter of ovarian tumors that the treatment of the pedicle should be by ligature, and accordingly we will find that all cases treated by ligature will be good surgery, and the man who attempts to treat by the clamp outside would not be judged a good surgeon by the medical profession, and on the witness stand would be handled pretty badly; there is but one opinion in regard to the treatment of the ordinary ovarian pedicle in laparotomy. But there is a variation of opinion concerning the ligatures; some use Japanese silk, some Chinese silk; some plain and some braided silk. Some operators are so strenuous that they will operate only with one kind of silk, while others will only operate with catgut. I saw a gentlemen in the East a short time ago, who believes that all the ovarian pedicles should be treated by catgut ligatures and nothing else, for the reason that suppuration may follow the use of silk whereas catgut is absorbed. That man going on the witness stand with this kink in his mind would testify very strongly against any one who used silk ligatures.

In regard to the treatment of the pedicle of uterine tumors, in cases of myomectomy there are two ways, one is to treat the stump in the intra-peritoneal way, and the other is the extra-peritoneal way. One making a covering of the peritoneum over the stump, stitching it tightly and dropping it back; the other is to bring it forward, anchoring it to the abdomen and letting it slough off. These two methods are very satisfactory, but they both have their defects. We are in a stage of transition concerning all these things.

Concerning ligatures: Not only in the abdomen, but for the treatment of the wound silk is used a very great deal, and so is catgut externally; the majority of the profession I think use nothing but silk, and they use the silk with one sweep through the mural tissues on both sides of the incision in that way including in the loop the skin and all tissues to the abdominal cavity. Another way to close the abdomen is to make three banks of stitches, first sewing the peritoneum down, then running the same ligature back again taking the connective tissue and the muscles through up to the upper angle of the wound, and then, with silk, bringing the skin together in three banks of stitches. I saw a gentleman who had done this operation a hundred times and never had had a hernia, and he believes that is the classical way of doing it; if that man should go on the witness stand and give evidence he might hurt those of us very much, whose method, varying from his, chances to be followed by a ventral hernia.

The toilet of the peritoneum is another point we will consider. In abdominal surgery absolute cleanliness is required, any uncleanness is reprehensible; I think there is but one opinion

on that point. Next, in regard to drainage, shall we drain or not? I believe there are cases appropriate for draining, and cases that do not call for it, but we will find that a drainage advocate will claim that all cases should be drained. But the man who is best posted on this question will on general principles usually have as little foreign substances in the abdomen as possible, and for this reason: The pressure of the organs against the drainage tube permits the formation of a fistula, and in that way we have intestinal fistulas opening into the abdomen followed by peritonitis. So you see there is something to be said against the drainage tube. I think in some cases a good method of drainage is through the vagina.

In regard to the after-treatment a great deal can be said. I can scarcely stop to go into the details, but on the first day after a laparotomy the fear of hæmorrhage is entertained, and on the second day the well-marked symptoms of peritonitis may come on, and if the physician is ignorant of this he may not employ the usual means of treatment. On the third day we are likely to get sepsis, and the man who does not know about this fails to recognize the condition, and in that way the patient may die, and this may lead to a mal practice suit.

All that can be said about these cases is that very little comparatively is well settled in regard to them.

DR. C. T. PARKES: It is hardly necessary for me to occupy your time on a subject which has been handled so perfectly by Dr. Etheridge. He has opened so many questions for discussion that it would be impossible to go over them all if we talked a month. I agree with him entirely in the rather positive assertion he makes that doctors are dangerous men, and they are more dangerous to themselves than to most other people. Especially is a doctor a dangerous man when he gets to be a very positive man, when he has had so much experience as to get into a rut; has had so many successful cases that he knows he is going to have a good result—and perhaps does generally get good results whatever the case. And that brings to us the thought that the method of doing things is of immense advantage. It does not make any difference whose method it is, the thing for the individual to do is to make it his method, and if he knows all about it—all about its peculiarities—that method is going to succeed. Medical men who get into the habit of being dependent upon themselves as to their methods will, I am sure, get better results by that means than by any other, but when they do that, they should always feel that it is owing to the fact that they have practiced in this way that they have become successful, and should believe that their friends and associates with other plans are doing as well as themselves.

I am interested a little bit in the subject of gun-shot wounds of the abdomen. I do not believe in statistics; you can prove anything by statistics, even a fact. I am quite sure that Dr. Etheridge in his quotation of statistics has taken them from the monograph of friends of mine in New York, Drs. Stimpson and Manley. Apparently they have collected all the bad cases, and, just so as to not make it too bad, they have put in a few good cases. People would not believe them if they said all the cases were fatal. That is all right. Doctors are apt to make their side of the question the most reasonable side if they can; that is all right too. There is no question but that the doctor is responsible always when he takes human life in his hands, but there should be a little liberality shown him when he takes a case of this kind, in which the life of the individual is absolutely gone, as in the vast majority of cases of gun-shot wounds of the abdomen; certainly if it is a fatal wound, he should not be blamed if occasionally he happens to lose a case of gun-shot wound of the abdomen.

The profession is apt to be elated about everything a little new, and go wild over it, and the same is true with reference to operations for gun-shot wounds of the abdomen. When laparotomy for this injury was first advocated by myself, everybody began to operate upon individuals who had received gun shot wounds without remembering that he who advised this method of opening the abdomen to treat these injuries had asserted positively that in his belief the majority of gun-shot wounds of the abdomen were fatal. The fatal injuries were not the ones we were after, but cases like the ones we often met with in hospital experience, in which the patient dies, and upon a post-mortem examination it was found that there was only a small wound, or two or three holes in the intestines which caused death, and they were separated from security only by the thickness of the abdominal walls. No man can tell what is done in the peritoneal cavity when a bullet has penetrated it until it has been opened; and while we must ask our legal friends to be a little liberal with us in these cases, I certainly agree with the author of the paper, that the item of abdominal surgery is entitled to more support from the general profession than perhaps that in connection with any other part of the body. It is the *terra incognita* of surgical practice. All general surgeons know how impossible it is for us frequently to tell the character of a simple tumor beneath the skin, and how are we going what is the character of a mass in a person's abdomen that fills it to such distension that we can find no signs of the existence of the ordinary organs in it? And how is a man to tell of those conditions which produce death many times, and yet are so simple in their specific development that they cannot be discovered without

opening the abdominal cavity? A doctor always takes a risk, and that is part of the nobility of the profession.

DR. W. E. CLARKE: At this late hour the only thing that I wish to refer to in the matter of abdominal surgery is the size of the incision. In my opinion, more injury can be done through a small one, in consequence of the shock produced by the traction and the abscesses that might result from the bruising of the parts, than would follow if the opening were sufficiently large to enable the surgeon to operate readily and with less violence.

DR. ETHERIDGE, in closing the discussion said: I have nothing additional to say beyond mentioning a characteristic case that recently came up in the courts. One man shot another and was taken and held until the result to his victim could be ascertained. The wounded man was taken to the hospital and had the holes in his abdomen sewed up and promptly died. The case came to trial and the defence was that the man came to his death at the hands of the surgeons. Thus we see that matters may assume a most grave aspect in abdominal surgery, and which at once put medical men upon their metal to defend themselves. I mention this circumstance to show the indirect possible bearing of legal responsibility in laparotomy.

A REMARKABLE CASE.

BY W. J. GALBRAITH, M.D.,

PROFESSOR CLINICAL SURGERY, OMAHA MEDICAL COLLEGE, VICE-PRESIDENT NATIONAL ASSOCIATION RAILWAY SURGEONS, VISITING SURGEON ST. JOSEPH'S HOSPITAL, AND CONSULTING SURGEON IMMANUEL HOSPITAL, OMAHA, NEB.

Incredible as it may seem, I trust the readers of THE JOURNAL will not consider me a fit subject for an insane asylum in reporting what I sincerely believe to be a fact. I most cordially invite any member of the profession to examine this unique pathological freak with me and trust you will avail yourself of the invitation. I fully appreciate the amount of criticism I will receive in reporting this case, and I realize that you will take the same version of the case that I did before I examined her. Notwithstanding I had good authority regarding her malady, I could not for an instant entertain the statements in any other light than those applied to a case of pure and adulterated deception; but since my examination and two months constant care I have changed my views, and feel that I am fully prepared to substantiate my statement by submitting the patient to any examination or test you may choose to make, and, moreover, I trust that many of you will feel sufficiently interested in this case to make a personal examination.

Mrs. M., aged 26, married five years, mother of one child two years old, medium height, light

complexion and of rather a nervous temperament, has attended one course of lectures in the Woman's Medical College at Chicago in the fall of 1889. On or about the first of December, 1889, she was taken sick with peritonitis and was removed to the Woman's and Children's Hospital, where she remained several weeks.

Her statement as regards her temperature at that time corresponds with one received from some of the attending physicians in Chicago.

I will give only a brief history of her case before coming under my charge. After her recovery from the attack of peritonitis while in Chicago, she returned to her home in Kearney, Neb. On or about the 12th of April, 1890, she was again taken down with a severe attack of general peritonitis. Her family physician, Dr. Duckworth, was called, and after making a careful examination satisfied himself that there was an abdominal or tubal pregnancy. A tumor the size of a fetal head could be mapped out over the region of the left tubes and ovary. The treatment following his first visit consisted of hot fomentations applied over the abdomen and the hypodermic injection of morphia. The following morning the Doctor was again called to see the patient who complained of pains similar to those of labor. After a vaginal examination had been made, the Doctor was somewhat surprised to find a foreign body engaged in the cervical canal near the external os. He procured a pair of long and narrow-jawed forceps and removed the body, which proved to be a scapula of a four months old fetus. The pains increased in severity after its delivery. A half a grain of morphia had been given hypodermically when several more bones were delivered in the same manner. The patient became somewhat exhausted and complained of being very feverish; after an examination of the radial pulse the Doctor assured her she had no fever as her pulse was only 62, and in order to satisfy her attempted to take her temperature. The thermometer was placed under her tongue and left there about two minutes when, upon its removal, the mercury was found to be at the top of the thermometer, which registered 112° F. Believing he had not properly shaken the mercury down, he took particular pains in doing so, and again placed the thermometer under her tongue, holding the end with one hand; in a short time he removed it, and to his surprise found it registered the same as before. Again shaking it down he placed it under the tongue and watched the mercury rise to the top almost instantly.

This was too much for the Doctor to stand, and as he expressed himself, "I believe I or the thermometer is crazy." He immediately dispatched a messenger for his partner, Dr. M. A. Hoover, to come at once and bring two or three Hick's thermometers along with him. After the pecu-

liar circumstances were explained to Dr. Hoover, by his partner, they immediately proceeded to try the new thermometers,—placing one in the axilla and one under the tongue. This resulted in a repetition of Dr. Duckworth's experience. Repeatedly the temperature was taken and with the same results.

The doctors wired Chas. Truax & Co., of Chicago, to forward them a fever thermometer that would register 125° F.; after some delay the new thermometer arrived and they commenced to keep an hourly record of her temperature. On the first trial the thermometer was found to register 3° below normal; the same evening it rose to 107° F. The peritoneal inflammation had by this time almost subsided, but the removal of bones continued the same. On the following day, after a chill, her temperature was taken, and to their horror they found the mercury had risen to the top of the thermometer, which registered 125° F., in less than one minute. Satisfying themselves that they must have a thermometer that would register higher, they again wired Chas. Truax & Co., of Chicago, to have a thermometer made that would register 150° F. On the arrival of the new thermometer, or within a few days, her temperature was found to register 145° F.

I was invited to see the case by letter, but made no reply to the same; the case continued on its peculiar career for several days, when Dr. Hoover made a visit to Omaha to consult me in regard to same. I assure you I felt sorry for him, as I supposed he had "slipped a cog" and his mental equilibrium was somewhat impaired. I advised him to return home and explained to him that he certainly had been deceived by a shrewd and hysterical woman; also advising him to say nothing to any one else. In a measure he accepted my advice and returned home, but continued writing me about the wonderful case and insisting that I should see her.

On November 6, I was telegraphed to come at once to see this case and, in order to satisfy the doctors, I determined to go, but believing that I was going on a "wild goose chase."

I equipped myself with a chemical thermometer, borrowed from Mr. Hodges, Chief Chemist of the Union Pacific Railway Co., which I had standardized, and obtained a certificate of its correctness, then inviting one of my colleagues, Dr. J. H. Peabody, of Omaha, to accompany me, proceeded to see this wonderful case.

On our arrival the temperature was found to be two and two-fifth degrees below normal; this, of course, somewhat surprised us, but in less than two hours we were more surprised to find the thermometer had reached 117° F., and at midnight, following a chill, the mercury registered in the axilla 145° F., and at the same time registering 125° F. under the tongue. In less than thirty

minutes the temperature in the same localities had fallen to three-fifths of a degree below normal, followed by sweating and a slight delirium. You can imagine that I was somewhat puzzled, and immediately apologized to the doctors. I could not believe my own eyes, and I assure you that Dr. Peabody was in the same condition. I thought that some form of heat must have been used or that she, in some manner, had tipped the thermometers upside down, unknown to me, or that, possibly it might be accomplished by some muscular action with which I was not familiar.

The following morning the patient was placed in a chair, all clothing removed and a careful examination was made of her mouth and axillary region, every possible precaution taken in order to prevent any deception, and holding the end of the thermometer so that it could not be tipped in any way, we again proceeded to take her temperature; but, gentlemen, the result was the same, the thermometer under the axilla registering 137° F. while that under tongue registered 131° F.

Another peculiar condition is that when her temperature reaches 140° F. or more her pulse is slow, 60 or 70 a minute; when her temperature is normal, or below normal, her pulse runs from 100 to 120.

The axilla and mouth are the two points on her body that register the highest. I have seen the axillary temperature 131° F., while under the flexure of the knee her temperature was below normal. Again, I have seen the temperature under the tongue register 6° F. below normal.

The case has now been under my charge for nearly three months. The highest I have ever seen her temperature was 151° F., while the nurse's record in the hospital shows it to have reached 171° F.

She has been delivered of over 1,000 pieces of bone; very few, however, are perfect, the most of them being deformed. Her general health seems to be quite good, considering her long and tedious sickness, and when she is free from peritoneal inflammation, is able to be up and about the house. At this writing, February 2, she is confined to her bed with one of her attacks of peritonitis.

There is no special time for her temperature to rise; it is usually preceded by a chill.

I have no theory further than I believe it to be some chemical change or combustion that takes place in the lymphatics, as its elimination is very speedy.

I deem it unnecessary to fill a dozen pages with a record of her temperature, as it is almost constantly changing.

DR. HENRY BACON, of Jacksonville, Fla., has been appointed Surgeon-General of that State.

MEDICAL PROGRESS.

Therapeutics and Pharmacology.

KOCH'S TREATMENT OF TUBERCULOSIS: GENERAL RESULTS.—DR. J. AMANN, of Davos, says (*Centralbl. f. Bakteriologie u. Parasitenk.*, No. 1, Band ix, January, 1891), that since November 17, there have been in Davos 400 cases of phthisis treated by Koch's method. Of 288 patients whose sputum he examined, 198 have been so treated. He examined the sputum of these latter sometimes once a day, sometimes once every two, three, or six days. He comes to the conclusion that the treatment has a most marked effect on the tuberculous tissues of the lung, and gives the following points of evidence in favor of this statement: The quantity of expectoration after the inoculation reaction is, as a rule, increased, in one case from 30 cubic centimetres to 140 cubic centimetres per diem. The number of tubercle bacilli in the sputum is also increased, in some cases the bacilli becoming very numerous where before it had been almost impossible to find them. In about 70 per cent. (134 out of 198), this increase was observed. There was only slight diminution in a very small number of cases. He also considers that the bacilli are considerably altered in form, the rods are broken down into micrococci, and abnormal forms are pretty frequently met with; the tubercle bacilli under these conditions lose, to a certain extent, their power of retaining the staining fluid in the presence of acids. The quantity of elastic tissue found in the sputum was considerably increased in about 40 per cent. of the inoculated cases. All these changes he attributes to the action of the tuberculin on the young tuberculous tissue, which leads to its rapid breaking down.

At the fourth general meeting of Russian medical men at Moscow, Dr. Nikolai S. Kishkin (*Tratch*, No. 2, 1891, p. 49), read a report of seven cases of pulmonary phthisis treated after Koch's method in Professor M. P. Tcherinoff's clinic, in Moscow. The observations lasted in four cases five weeks; in two, four weeks; and in one, three weeks. In all the cases the symptoms were "quite distinct, but not very severe," the general state being more or less satisfactory. In five no fever existed, while in two there was slight pyrexia. The effects of the injections were as follows: 1. The percussion phenomena remained unaltered. 2. The auscultatory signs in two did not undergo any changes; in two the râles somewhat diminished; in one they disappeared almost completely; in one they disappeared entirely; and in one they disappeared from their former situation, to appear in another. 3. Cough, expectoration, and the number of bacilli in the sputum showed no alterations in two cases, while in the remaining five they de-

creased. 4. The weight in four cases increased, but in three fell somewhat. On the whole, of the seven cases, four slightly improved, the amelioration being both local and general, and apparently due to the injections alone. The reaction, though invariably present, varied greatly both in the time of its appearance (developing in some cases in five, and in others in twenty-four hours after the injection), and in its intensity (oscillating between a very slight elevation of the temperature with trifling general weakness, and severe prostration accompanied by a rise of temperature to 41° C.). The local reaction was different in different cases. Dr. Kishkin feels sure that such differences were dependent solely upon individual peculiarities, having no relation whatever to the dose of the lymph or the extension of the tuberculous process.

DR. FEDOR I. LOMINSKY, of Kieff (*Tratch*, No. 1, 1891, p. 23), reports ten cases of phthisis in which he tried Koch's treatment, injecting from 0.001 to 0.006 gram every other day. In one of the cases, large cavities were present in the lungs, the remainder presenting either incipient symptoms or only slight destruction of the pulmonary tissue. The lungs, respiration, pulse, and temperature, were carefully examined every three hours. The following are the principal results of the observations: 1. After 0.001 g. doses, the reaction was, as a rule (nine cases), either absent altogether, or limited to a trifling rise of temperature (which, after all, might have occurred quite independently of the lymph). A considerable rise was observed only in the patients with large excavations. 2. In incipient cases no reaction could be noticed even after 0.002 g. or 0.003 g. doses (in one even after 0.006 g.). In more advanced cases, however, these doses were followed by a slow febrile rise. The latter began from four to twelve hours after the injection, and reached its maximum in from six to fourteen hours, keeping at the level for three hours, after which it gradually fell to normal. In all but one case, on the following day the temperature either remained normal or rose but slightly. In the severe case, however, a secondary elevation occurred, which was still more considerable than the primary one. 3. In some of the febrile patients the injections modified the type of the fever. 4. The reaction, when present, was accompanied by oppression about the chest, increased dyspnoea and cough, and sometimes hemoptysis, the symptoms being in some so intense that the patients declined further treatment. Simultaneously, the expectoration became more abundant, and the sputa thinner, the number of bacilli sometimes decreasing. In one patient albuminuria also supervened. Dr. Lominsky describes a case of faucial, laryngeal, and pulmonary tuberculosis, in which the following "interesting reaction" was observed. Be-

fore the treatment the faucial changes were limited to considerable congestion of the pillars, with two white patches on the left one. Four injections were given in the course of a week, the dose being on the first occasion 0.001 g., and on the subsequent three 0.002 g. Shortly after the first injection the congestion increased and the tissues became infiltrated, while there gradually appeared numberless greyish nodules which rapidly coalesced, broke down, and formed ulcers, until the whole fauces and sides of the pharynx were transformed into a single extensive ulcerated surface, covered with a yellowish grey coat. At the same time, the faucial and laryngeal pain became aggravated to such a degree that the patient "almost ceased to take food," while his subjective state grew worse. Though no rise of the temperature occurred, the patient lost 3 pounds during the treatment.—*British Medical Journal*.

MIXTURE FOR VENEREAL WARTS.—M. CIRO URRIOLA (*La Semaine Médicale*) recommends a mixture of salicylic acid two parts and acetic acid thirty parts in the treatment of venereal vegetations. The mixture is applied with a fine camels-hair pencil once or twice daily. Usually but two or three treatments are required to cause the greater portion of the vegetations to disappear. The writer claims that the application causes but slight and transitory pain, and that it is preferable to all other modes of treatment.

ZYZIGIUM JAMBOLANUM.—This drug, after a latent period of some years, seems destined to again be put upon trial, notwithstanding its inefficiency, as was shown some years ago. ROSENBLATT in *Tratch* (*Nouveaux Remèdes*, Feb. 8, 1891), reports a case of diabetes in which there was marked amelioration of the symptoms, and a diminution of the amount of sugar in the urine. The drug was administered in the form of powder, three to fifteen grams in twenty-four hours, and the fluid extract three to twenty-two grams daily.

Medicine.

PRACTICAL COMMUNICATIONS REGARDING THE TUBERCLE BACILLUS.—DR. BLIESENER (*Deut. Med. Zeit.*) recommends the following as a good method of staining the bacilli: Prepare a solution containing, fuchsin 1 part, absolute alcohol 10 parts, carbolic acid 5 parts, distilled water 95 parts. The sputum to be examined is spread thinly upon a cover-glass, passed rapidly through the flame of a spirit lamp and then laid upon a small piece of tin with the prepared side up. A few drops of the above solution are placed upon the glass and the tin placed over a spirit lamp until bubbles are given off. Remove the flame and allow the glass to cool, but not to dry, if necessary add a drop of the solution. The cover should

then be washed and floated upon the surface of the following solution contained in a watch glass: Methyl blue 1.5 parts, distilled water 100 parts, sulphuric acid 25 parts. Allow it to remain upon this solution for about one minute, then wash and mount. With this method the tubercle bacilli are stained a bright red upon a light blue ground.

The *Münchener Med. Wochenschr.*, No. 1, 1891, gives the following account of Biedert's method of finding the tubercle bacillus in suspected fluids: One drachm of the fluid is mixed with an equal part of water and 7 or 8 drops liq. natr. caust. (Ger. phar.). The mixture is then boiled, four drachms of water added and again boiled until the fluid is of equal consistence. If the fluid is not perfectly thinned by this procedure, more water can be added. The liquid should then be placed in a conical glass and set aside for two or three days, when the bacilli will collect in the lower portion of the glass, which is examined in the usual way. By this method it is often possible to detect the bacilli when the ordinary examination gives a negative result.

It is apparent that a negative answer to the question, "Is the tubercle bacillus present in a given specimen?" is much more difficult than a positive one. If they are looked for and found, that settles the matter, but if they are not found, have we simply overlooked them? The method of Biedert, as given above, unquestionably adds to the certainty with which we can find the bacilli, and thus is an additional precision in diagnosis. The present active therapy of tuberculosis lends additional interest to these observations.

DR. BERNHARD MEYER (*Centralblatt für klin. Med.* Feb. 7, 1891) has contributed an excellent study of the methods of examining various secretions and excretions for the presence of the tubercle bacillus. He especially recommends Biedert's method in examining the sputum. In his hands it has often shown the presence of the bacilli when the repeated examinations with the ordinary methods failed to show them. If the bacilli are *not found* with this method we cannot absolutely affirm that they are not present, as was shown in a case of Prof. Fraenkel's, in which the symptoms, cough, expectoration, fever and emaciation, pointed to a phthisical condition, while repeated examinations of the sputum, extending over a period of six months, failed to reveal the bacilli, and yet the patient died with the typical symptoms of florid phthisis. The writer claims that while the method of Biedert is not absolute, yet where it is employed in investigating the sputum, and no bacilli are found, we may affirm with reasonable certainty that there is no tubercular process in the lungs. He thinks that inoculation is the only method of absolutely determining the presence or absence of the bacillus.

In eleven cases of pleuritis the exudate was examined for the bacilli, and in one case of empyema the bacilli were found in great numbers. In no case of either primary or secondary serous pleuritis was the bacillus found.

Two peritoneal exudates were examined, one with negative and the other with positive results. The former was a serous exudate from a case of pulmonary tuberculosis, with abdominal symptoms. The second was a purulent exudate.

The writer has determined the presence of the tubercle bacillus in urine that was perfectly clear and free from albumen. In examining this excretion Biedert's method, or one devised by the author, may be employed. The latter consists in mixing the urine with thymol and so arranging a small filter that the urine shall fall drop by drop upon the centre. The surface of this small area is then examined in the usual manner.

The presence of the bacillus in feces is even easier to determine than in sputum, therefore the writer has not had occasion to use the method of Biedert. Out of eight cases examined that came to autopsy six were found to have a tubercular process in the digestive tract. The two other cases were those of advanced pulmonary tuberculosis, and the presence of the bacilli is accounted for under the theory that some of the bronchial secretion had been swallowed.

A case is described in which secretion from the middle ear was examined and the bacilli found. Under the influence of Koch's remedy the bacilli increased, and then diminished, finally disappearing with the secretion, and the closing of the opening in the drum. The concurrent pulmonary tuberculosis of this patient was not in any way affected by the injections.

TUBERCULAR AFFECTIONS OF THE SKIN TREATED BY KOCH'S LYMPH.—*La Semaine Médicale* of February 14 contains a table of thirty-eight cases treated in the Paris hospitals and by various surgeons, as follows: E. Vidal 2, Vidal and Besnier 5, E. Besnier 9, Fournier 2, Hallopeau 14, Tenneson 5, Quinquaud 1.

Of course, the number of the injections varied, as well as the dose. In twenty cases there was a violent reaction with high fever and great prostration; in fifteen cases the reaction was moderate, in two variable, that is, differing from the usual type, and in one, weak.

Local reaction in the affected part was described as very intense, erysipelatoid in character in eight cases, and in one other case as leading to a vast phlegm requiring surgical interference. In nine cases the reaction is spoken of as lively, in sixteen as moderate, in two as slight, and one in which it was absent.

The results in these thirty-eight cases were: Much improved, 1; improved, 12; slight amelioration, 11; negative in fourteen.

TREATMENT OF LEPROSY WITH KOCH'S LYMPH.—DR. GOLDSCHMIDT (*Berliner Klin. Wochenschr.*, No. 2, 1891) has treated five cases of leprosy, four of the tubercular form, and one of anæsthetic-paralytic type. At the close of his article he advances the following conclusions:

1. Doses of less than one mg. have little or no effect.
2. One mg. in the first three cases produced a general reaction after twenty-four hours; in two cases there was local reaction.
3. Larger doses, under 0.01, produced a high temperature (excepting case 5), and in another (case 1) a very remarkable local reaction, that is still under observation.
4. The remedy gives a reaction with lepra as well as tuberculosis.
5. He cannot exclude the possible presence of a tubercular foyer in the first four cases.
6. The immediate contact of the remedy with leprosy skin seems to cause more irritation than with healthy integument.
7. The leprosy mucous membrane showed no reaction.
8. Nervous lepra showed general and slight local reaction.

Surgery.

REMOVAL OF THE LEFT LOBE OF THE LIVER.—The number of operations upon the liver in which a portion of the organ has been removed are not so great but that special interest attaches to any case.

LUCKE of Strasburg, (*Centralblatt für Chirurgie* Feb. 7, 1891) reports the case of a woman who presented a small, firm tumor in the epigastrium. There was pain, vomiting and considerable disturbance of the general health. A careful examination of the stomach and its contents showed an apparently healthy organ. A diagnosis of cancer of the left lobe of the liver was made and an operation determined upon. On opening the abdomen the tumor presented and was readily brought through the wound and transfixed. It was then encircled with an elastic ligature, the wound closed as far as possible and a dressing applied. Three times the dressing was changed and each time the ligature was tightened, finally the tumor was separated and the constricted surface of attachment was thoroughly canterized. The abdominal wound healed slowly. There has been no return of the disease.

RESECTION OF THE SPLEEN.—BARDENHEUER (*Deutsche med. Wochenschrift*) describes an exceedingly interesting case. The patient, 47 years, had complained of some indistinct uterine and stomach disturbance. Upon examination a small tumor could be felt in the true pelvis, it was not readily movable and the writer concluded that he had a small ovarian cyst with adhesions. The incision was made with possible reference to an

intra-ligamentous cyst, but as a diagnosis was not possible by the extra-peritoneal method, that membrane was opened, when much to the operator's surprise he found that the tumor was a small cyst of the spleen. The organ was grasped by an assistant and the tumor cut away. But little hemorrhage followed which was easily controlled by the actual cautery. The organ was then replaced, and the wound closed. Seven weeks later the patient was discharged. An examination of the cyst showed that it was of parasitic origin.

Obstetrics and Diseases of Women.

INFLAMMATION OF THE CLITORIS.—PHILIPPEAU (*Gazette Gynécologie*, February 1, 1891) reports the case of a woman who consulted him about one week after menstruation for an itching of the upper part of the vulva. On examination the vulva was found to be normal in color; no discharge from the urethra or vagina. Uterus healthy. The clitoris was enlarged, reddened and excoriated, the vulvo-vaginal glands were normal. The writer could not refer the condition to any exciting cause. The patient had had two other attacks within six years, from which fact he refers the peculiar inflammation to a rheumatic origin. Under soothing lotions and the application of cocaine the inflammation rapidly subsided. The case is certainly deserving of notice as primary inflammation of the clitoris is a very rare occurrence.

VOMITING OF PREGNANCY.—The *Journal de Médecine* recommends the following for vomiting of pregnancy: Tr. iodine and chloroform, equal parts, five drops to be taken morning and evening, in a little water, with the repast.

Hygiene.

HYGIENE IN FRANCE.—Recently the French Chamber of Deputies have considered a general law governing workers in factories, child labor, etc. M. DE MUN proposed an amendment providing that women should not be allowed to work the first four weeks after confinement. The proposition created a lively discussion, the general tenor of which was to the effect that the private life of citizens should not be interfered with to the extent proposed, and that the fixing of an arbitrary limit of four weeks was not wise, as many would be able to be at work long before that time, while others would be incapacitated far beyond the limit. One member proposed that compensation by the State be given to the extent of one franc per day. The amendment was finally tabled by a decisive vote.—*Le Bulletin Médical*.

SATURDAY, MARCH 21, 1891.

THE GRADUATING AGE IN MEDICINE.

In the Seventh Report on Medical Education just issued by the Illinois State Board of Health is a paragraph that reads as follows:

Under the schedule of two-year courses and three years' study the earliest age at which a student can be graduated is 21 years. The addition of one year each to the time of study and the college term would seem to justify the limitation of the minimum age of graduation to 22 years. This is a matter that the boards of examiners and the colleges would do well to take under consideration.

Following this paragraph is a table showing the ages of graduation of 5,719 graduates—5,497 of American colleges, 82 of Canadian, 32 of English, 98 of German and 10 of Swiss colleges. Of the 5,497 American graduates 5,214 were males and 283 females. The number from the Swiss colleges is so small that it may be eliminated. The following shows the numbers up to 40 years of age, the males and females being given separately for the United States:

Age.	United States.	Canada.	England.	Germany.
19	9 0	0	0	0
20	79 2	0	0	0
21	233 5	12	4	9
22	431 11	8	6	6
23	506 10	9	4	15
24	507 11	12	5	13
25	496 15	10	2	12
26	409 15	6	2	10
27	378 11	7	2	7
28	322 18	4	2	2
29	255 21	2	2	2
30	218 15	1	2	5
31	178 16	2	0	4
32	175 4	0	0	1
33	161 9	4	0	3
34	128 18	0	0	2
35	128 12	4	0	3
36	94 12	0	0	2
37	81 9	1	1	0
38	67 4	0	0	1
39	44 7	0	0	0
40	47 10	0	0	0

From these figures it is seen that the greatest number for any age was 551 for 24 years, and that the two next highest numbers are 544 for 23 and 535 for 25 years. After these came 462 for 22 and 442 for 26 years. The number of graduates at 21 years is lower than at any subsequent age until 30 years. Omitting the numbers of graduates at 19 and 20 years, the total from 21 to 30 inclusive is 4,073, out of a grand total of 5,719. Of the total graduates from 21 to 30, then, the percentages at different ages are: 21 years, 6.43; 22 years, 11.34; 23 years, 13.35; 24 years, 13.52; 25 years, 13.11; 26 years, 10.85; 27 years, 9.94; 28 years, 8.54; 29 years, 6.92; 30 years, 5.91. It will probably never occur again in this country that so large a proportion of medical men will graduate after the age of 30.

The question is, Is it best to raise the minimum age for graduation to 22 years? The figures above are given merely as a part of the data upon which to discuss the question. All that they show is that of the known ages of graduation of 5,719 graduates, fewer graduated at the present minimum age than at any later age up to 29, inclusive. The reason for this may help answer the question at issue. In order to graduate at 21 years after two courses one must enter college at 19, which, we believe, is below the mean age of the seniors in the better class of academic institutions. This leaves no time for the one year of medical study (or reading) before entering a medical college. On the two-course and three years' study schedule, then, the average student cannot be graduated until after he is 22 years old, even if he enter upon the study of medicine as soon as he leaves the academic college. There are some that do not graduate, however, but begin the study of medicine before the time at which they would complete their academic course. On the other hand, a considerable number of academic graduates do not begin the study of medicine immediately after leaving college—often for financial reasons. It is not improbable that young men having no more than a common or high school education enter upon the study of medicine a little later than do college graduates. The foregoing remarks apply to this country only. In other countries young men go into business—including the practicing of professions—later than in this country. They may, on an average, begin the study of medicine about the same age,

but the term of study is much longer. Yet it is probable, almost certain, that the foreign student begins the study of medicine later than the American, and in addition to his maturer years and mind he has a better education. As a rule medicine has been the life-aim of the foreign medical student since his youth. In America the study of medicine is often the result of a sudden determination, a reverse of fortune, or is decided upon in early manhood.

It is now agreed, however, that the term of medical study in this country shall be four years, including three courses of lectures, and a few colleges have adopted four courses of lectures. In order to comply with these requirements the student must begin to study medicine at 17 in order to graduate at 21. Very rare is the young man of sufficiently mature mind to begin the study of medicine at 17 years; so rare, indeed, that he may be left out of consideration. The study of medicine, properly carried on, demands a well-developed reasoning faculty rather than the exercise of the faculty of memory. Up to the age of 18 or 19 years, often until later, the whole system of education, as at present applied, is chiefly restricted to certain dogmatic facts, rules, laws and axioms. From early youth the pupil has learned grammatical rules only to find that they have exceptions, which are sometimes so numerous that the rule itself seems an exception. So thoroughly is he saturated with this sort of knowledge that he pictures a law of science—nature—as something that has exceptions; and he is quite ready to believe that the law of gravity has exceptions. The methods of inductive and deductive reasoning are unknown to him, and whatever logical faculty he may have is always silenced by the voice of what he considers "an authority."

Such a young man is not yet even in the lowlands of medicine, but in the vast swamp of unreason, from which he can be rescued by nothing but a scientific course, and preferably one preparatory to the study of medicine—such as is now offered by some of the larger universities. It is, of course, better that such a course be substituted for a part of the regular academic college course, since in the latter much time is spent on subjects the study of which is of no assistance to the student of medicine or to the physician. The scientific course preparatory to medicine should occur

at least three years. It is doubtful, however, if it should be begun before the age of 15. Nothing is to be gained by forcing a mind. As between a hot-house mind and one of more natural growth, the latter will have the better development at the age of 30 years.

Taking all things into consideration it seems that the minimum age for graduation should be placed nearer the normal, at 22 years. The public and the profession would be the gainers by this, and the public more than the profession.

A MASTER'S INFLUENCE.

Such it is which moves our feelings and prompts the springs of eulogy to flow; and such it is which turns the eyes of a medical world towards a memory indelibly blended with the history of medicine and allied sciences. February 14th, the Hunterian Oration was given in the theatre of the Royal College of Surgeons, London, by JONATHAN HUTCHINSON; and quite coincidentally there was delivered at the London Institution the oration of the Hunterian Society for 1891, by FLETCHER BEACH, and entitled: "Psychological Medicine in John Hunter's Time and the Progress it has Since Made."

Jonathan Hutchinson compared the mind of Hunter with that of Aristotle of ages gone, and erected a tower of mental strength into which no third mind could enter. The tireless industry, the keen perception, the courage of conviction, the wonderful self-reliance and originality, the mental hardihood—all leading to, and being part of, that insatiable thirst for knowledge which so intensely characterized the man, left their markings upon the times after him, and we have to-day magnificent examples of the effects of this teaching.

It is the influence of master minds which stimulates the thinking world to-day—as, indeed, it always has done—and notwithstanding that those minds may have long since lapsed to dust again, yet the song of their glory and mighty achievements still echoes to our ears, and awakens that bright glow of a generous pride, and the warm impulse of emulation. Like in that spectral review of Napoleon, the medical learner of now may stand where the sifted utterances of the past may reach him, and be directed thereby to goals which Patient Toil and Genius command. It is the noble examples of yesterday and to-day

whose influence thrill throughout the great medical body, carrying it onward in its march of progress, and in its earnest seekings to alleviate the afflictions, and prolong the lives of brother mortals.

Well may we listen a moment to the echoes of a Hunter's teaching, the observations of a Jenner, or the analysis of a Cavendish; and yet all blended into the great stream of enlightenment which flows to us, and which we, in turn, are striving to enlarge.

LOSS OF LIFE BY FIRE-ARMS.

The Lancet offers editorially some considerations as to the much-needed legislation against an easily preventable cause of death, the promiscuous handling of loaded pistols. Even in this country where many men, and some boys, habitually "carry a gun" the legislation needed to circumscribe the habit and thereby save life, is extremely defective. The suggestions of *The Lancet* are in the main twofold, first, the registration of sales, including a prohibition to sell to minors; second, an exceedingly heavy tax to be assessed upon everyone who indulges in the luxury of habitually carrying the means of ready homicide. The American practice of giving a man a permit to carry a pistol, a right which in some of our cities is seemingly vested by law in the department of police, is a practice of very doubtful humanity, expediency or equity.

A COMPARISON BETWEEN SALICIN AND THE SALICYLATE OF SODIUM.

DR. ALEXANDER HAIG has recently read a paper before the Medical and Chirurgical Society of London on the comparative merits of these two drugs in the treatment of acute articular rheumatism. He bases his comparison on the relative power of the two drugs to excrete, or to stimulate the excretion of, uric acid. He has found that the salicylate of sodium has about thirteen times the excretory potency of the other drug, and he thinks he has seen that their power to interfere with the course of the disease has been approximately identical with their liberation of uric acid. His contention is that all those plans of treatment of acute rheumatism that have proved beneficial have been so in an exact proportion to their uric acid seceding power. According to Dr. HAIG'S

reasoning, acute rheumatism is caused by the presence of uric acid, primarily, in the blood and that being driven thence by a high acidity, it is precipitated in the joints, and that this precipitation of the acid, together with the fact of the non-destruction of the acid furnish us with the most manageable theory as to the inflammatory processes and pyrexia of the malady. The rise of temperature adds to the acidity and the precipitation of acid in the joints is more complete than in gout. There may be other causes besides pyrexia that will increase the acidity, such as suppressed perspiration and chilling, tonsillitis and other local inflammations, and the ingestion of acids and acid-forming foods, all of which are predisposing causes for rheumatic attacks. He also holds that the high arterial tension at the end of an attack is an indication of an excessive proportion of uric acid in the blood, and that, therefore, any cause that increases the acidity at that time tends to bring on a reprecipitation of the acid and a relapse.

SHOULD PHYSICIANS STUDY LATIN?

In the day when medicine was held to be one of the learned professions, and Latin an essential part of a gentleman's education, this would have seemed a superfluous question. Times have changed since then. The physician of the present time knows many things of which his predecessor of a century or two ago was ignorant, that are of more importance to his patients than a dead language, but even when liberally educated it is apt to be the case that he is less of what is called a scholarly man than those of corresponding standing in times when the requirements of strictly professional education were less exacting. That the gain has been, on the whole greater than the loss, there can be no doubt, and the question becomes more and more a serious one, which, among the ever increasing multitude of things that it is desirable for a physician to know, are essential, and which more or less superfluous.

No one who reads the medical periodicals, and understands Latin, can fail to be aware that a knowledge of it is not essential either to a marked degree of competence or to high professional standing. Whether a classical education would have been a help, in all cases, to those who have

succeeded without it, will probably never be known. The question of the comparative disciplinary value of such studies and others of more immediate practical application is one into which we do not propose, at present, to enter, but there is at least one drawback connected with ignorance of the language which is indisputable, and somewhat serious.

The technical nomenclature of medicine is a relic of the time when every educated man was expected to be familiar with Latin, not only as a written but a spoken language, and would incur more discredit by using it incorrectly than by mistakes in his own language. It is impossible for any one who is not acquainted with Latin to use such terms grammatically, and, although correct grammar may be classed rather among the luxuries than the necessities of life, it is something which, like clean linen, is rather expected of men in certain positions. When medical men in countries in which a classical education is an essential prerequisite to the study of medicine find that professors in our medical schools, and men otherwise of high standing in the profession, are unable to use the terms of their profession correctly, they are apt to draw unfavorable, and often unjust inferences as to their competency in other respects.

It is unnecessary to multiply instances; every one who understands Latin has met with plenty of them, and those who do not would be none the wiser. It may be enough to say, by way of example, that to speak of a woman's right labia majora is a mistake of the same kind as to speak of her right feet.

What is the remedy? Shall the doctors learn Latin, or shall they be provided with English equivalents for those terms to which they are now lacking, and compelled to use them? Either course would have its difficulties. With respect to the latter, a glance at the experience of another country may be instructive. In Germany, although physicians in general are acquainted with Latin, the patriotic feeling of some of them impels them to find or invent German words for those of foreign origin. In a large proportion of cases the substituted terms are literal translations of the Latin words. The essential absurdity of the present nomenclature is thus held up to view in all its naked deformity. "Egg-stem" for ovary is not so bad, and "thin-gut" and "thick-

gut" for the two divisions of the intestines are descriptive, if not elegant, but it is difficult to see the merit of "see-hills" for optic thalami, "knee-humps" for corpora geniculata, and "brain-leg-hood" and "brain-leg-foot" for the two divisions of the cerebral peduncles. If our medical terminology is to be reformed, it is to be hoped that it will fall into the hands of some one who will "reform it altogether."

EDITORIAL NOTES.

A DISTINGUISHING MARK.—A British doctor has lately contended in favor of a particular style of hat for physician's use. His argument is not made for advertising purposes; but to facilitate a proper recognition between men of the same class—as largely obtains in England between clergymen, and between barristers, from distinctive features of their costume. Other points are also advanced, such as a saving of time to the physician, and the prompt assistance which may be afforded in accidents by being quickly recognized among a mass of people.

We remember that these, and other arguments, were put forth some time ago by a physician in this country, who favored the wearing of an olive-colored button by all members of the medical profession.

It is feared, however, that plans of this character will beg adoption, for reasons which all will appreciate.

Apropos to this may be mentioned the uniform allowed the French doctor on State occasions. By a clause in a law of 1803, it was enacted that a plain Doctor of Medicine could wear at public ceremonies, or when giving evidence before a court of justice, a costume as follows: A black gown of bolting cloth (*etamine*), the back and front of which are of crimson silk bordered with ermine; a black coat *à la Française*; cambric bands, and a cap of crimson silk with a border of gold lace.

ASEPTIC URINE FROM SALOL.—M. Lacroix reports to the Paris Société de Pharmacie, that his experiments have demonstrated that the pyogenic bacillus cannot develop in the urine of those taking salol internally.

STATE CARE OF INEBRIATES.—The Legislature of the State of North Carolina has set aside a portion of the Western North Carolina Hospital

for the care and treatment of inebriates. This is looked upon as only a beginning of what will ultimately be a duly-appointed and properly-equipped asylum.

A COMRADE OF TYROTOXICON.—Prof. Victor C. Vaughan announces that a new toxic element has been discovered in cheese, differing from tyrotoxicon. As yet it has not been isolated, but has been found to be intensely poisonous.

HONORS TO HELMHOLTZ.—The 70th birthday of Professor von Helmholtz occurs on Aug. 30, 1891, and it is proposed to commemorate the event by presenting him with a marble bust, and the striking of a special medal to be bestowed upon physicists of eminence. It is desired to form an international committee for carrying out the scheme.

THE REPUTED CAUSE OF INFLUENZA.—Dr. Tezzier, of Lyons, France, claims that influenza is produced by a microbe, which he styles the strepto bacillus, whose habitat is putrid mud. That Russia is its home is, in his opinion, due to the fact that bad drainage, filthy streets and neglected barnyards are the rule, a condition particularly aggravated by swollen rivers and generally wide plains.

CREMATION IN LIVERPOOL.—The following resolution was passed by an overwhelming majority at a late meeting of the Medical Institution of Liverpool:

Resolved, That this society recognizes the advantages of cremation as a means of disposal of the dead, and considers the establishment of a crematorium in Liverpool, under suitable regulations, as free from objection.

It is stated that there are now about forty-two crematoria in existence throughout the world; and that the first crematorium of modern times was erected at Milan, Italy, in 1880. The practice of cremation will, therefore, be seen to have had a large and rapid growth.

MEDICAL ITEMS.

TESTIMONIAL TO VIRCHOW.—The friends and admirers of Dr. Rudolf Virchow in Great Britain have, according to *The Lancet*, February 7, undertaken the formation of a testimonial fund to enable them to unite with others of other nations in the celebration of the seventieth birthday of "the great exponent of cellular pathology." This event will take place October 13, 1891. Sir

James Paget was unanimously agreed upon, by the committee organizing the Fund, to be invited to take the chairmanship of the English branch of the movement. The editor of *The Lancet* adds: "The movement set on foot in Germany will doubtless spread to every country in the world, and we are glad to find that Great Britain will be represented." The nature of the proposed testimonial will include the presentation of a large gold portrait medal to Virchow himself, and bronze replicas of the same to members of his family and to some scientific institutions.

THE HUNTER MCGUIRE PRIZE ESSAY.—The announcement is made that the subject of Dr. Hunter McGuire's Prize Essay for 1891 will be "Pyelo-Nephritis." The prize offered is \$100.00 and is to be awarded during the session of the Medical Society of Virginia at Lynchburg, Va. The prize is only open to members of the Medical Societies of the States of West Virginia and North Carolina.

CONGRESS OF GERMAN SURGEONS.—The 20th Congress of the German Surgical Society is to be held in Berlin from April 1st to 4th, under the presidency of Professor Thiersch. It is proposed to give the first day of the meeting to Koch's treatment of tuberculosis, and the introductory address on this topic will be delivered by Professor von Bergmann. Patients and specimens illustrating the effects of the new mode of treatment will be shown in the University Clinic on the morning of Thursday, April 2nd.

MORTALITY EFFECTS OF THE LATE COLD WEATHER IN PARIS.—Vital returns of Paris plainly indicate the effects of the cold weather of the season just passed. Frost is reported to have set in on November 26th, and lasted without intermission until January 21st. Deaths from respiratory diseases were much increased, though the effect was not noticeable until some three weeks or more after the setting in of the cold spell; and the general thaw was followed by an almost immediate lowering of the death-rate.

THE COLONIZATION OF EPILEPTICS.—A bill has been introduced before the Legislature of the State of New York providing for the creation of a Board of Commissioners which shall have charge of the housing, and grouping under care, of epileptics.

TOPICS OF THE WEEK.

THE ETIOLOGY OF TETANUS.

In the last number of the *Annales de l'Institut Pasteur* there appears (from the Bacteriological Laboratory of Val-de-Grâce) a most interesting paper on tetanus by Drs. Vaillard and Vincent, which appears to throw very considerable light on the subject of tetanus, and to clear up a number of points and observations that have hitherto been enshrouded in obscurity. After describing the organism, and identifying it with that already made familiar through the papers of recent writers, the authors give it as their firm opinion that in cases of artificial inoculation of pure cultures it is always the poison introduced along with the bacillus, and not the organism itself, that acts upon the animal. This indeed seems to be probable, as they are able to prove that almost inconceivably minute doses of this poison, which they compare with snake poison, are quite sufficient to produce all the symptoms of most acute tetanus; in fact, it was almost impossible, from some of the cultures that they obtained, to administer a dose that was not lethal.

An exceedingly interesting feature brought out in the course of their work is that in no case was the poison developed as soon as the organism began to grow; in fact, gelatine cultures of the tetanus bacillus were never capable of producing toxic symptoms until liquefaction of the gelatine had commenced, when spores were demonstrated to have been formed, and when the peculiar disagreeable odor so characteristic of tetanus cultures had become perceptible. They associate both the odor and the peptonizing power with the formation of the poison in the cultures. That it was due merely to the presence of the spores that the material was poisonous they demonstrated by heating their cultures to a temperature of 62° C. for a short time (a temperature which is quite incapable of interfering with the vitality of the spores), when it was found that cultures so heated and introduced by inoculation into a rabbit or a guinea-pig failed to produce any tetanus, thus proving that although the spores are not killed the poison has been destroyed by the heat. The spores were proved to be living by making fresh cultures from them in artificial media; after a time they grew luxuriantly, and if left to grow eight or ten days produced another crop of the poison. By simply washing away the poison from the spores with distilled water they also obtained similar results, for, although the spores could still develop and form the specific poison in artificial media, they were, when inoculated, incapable of giving rise to any symptoms of tetanus. From the reaction to heat of a substance they were able to separate, and from its resemblance to the diastases in other respects, they conclude that they have obtained from tetanus cultures the true tetanus poison, a poison, however, that cannot be formed by the tetanus bacillus in healthy tissues. The microorganisms are here so rapidly attacked by the leucocytes that they are rendered *hors de combat* before they have time to form their poison.

It has for long been well known that the tetanus

bacillus could not develop in the tissues except, apparently, in the presence of other organisms, and the suggestion is offered that these other organisms act in one of two ways; they either paralyze the activity of the leucocytes, or they draw off, as it were, their attention and activity from the tetanus bacillus, thus allowing it sufficient time to develop its characteristic products. It is interesting to note that Drs. Vaillard and Vincent consider that in many respects the tetanus bacillus is extremely like the diphtheria bacillus, the method of action on and in the organism being essentially the same in the two cases, the above factors in all probability playing a part in diphtheria much as in the case of tetanus; and it is evident that in studying the one poison much light may be thrown on the other. Behring and Kitasato appreciated this fact, and combined their forces to work out the question of immunity in these two diseases. It is obvious, however, from a consideration of some of the points that are indicated in this paper, that there are many sources of fallacy that will have to be eliminated before the ultimate explanation of the condition of immunity in protected animals can be given. The facts that this poison is active in such extraordinarily minute quantities, and that the microorganisms are able to grow with such difficulty in the human tissues, allow us to hope that extremely minute changes in the blood may be quite sufficient to secure the alteration or breaking-down of the virulent poison, even when it has become diffused throughout the system. So long as the organism is localized to the wound, there is, of course, more chance of coping successfully with the disease, although here, as in other diseases, there always appears to be a possibility of the poison exerting such a paralyzing influence on the cells that usually take up foreign substances, that secondary septic conditions may be liable to occur even when the action of the tetanic poison can be antagonized so far as its primary effects on the cells are concerned. One question appears to be set at rest, and that is, as regards tetanus and diphtheria, the ptomaines have had their day, whatever may become of the products of other organisms. It may be accepted that here, at any rate, we have some subtle poison which, although it has not yet been actually separated, has become so far isolated that it may be taken as proved that it is not an alkaloid or basic poison. A most remarkable feature is that, in peptonizing gelatine with the filtrate from a meat-broth culture of the tetanus bacillus, the poisonous properties are lost to a certain degree in direct proportion to the amount of gelatine that is peptonized; this, taken in conjunction with the fact that the properties are not developed until the gelatine begins to liquefy, has led Drs. Vaillard and Vincent to suppose that the same agent that peptonizes the gelatine is the active agent in bringing about the development of the toxic symptoms of tetanus. — *The Lancet*.

THE INVESTIGATION OF HYPNOTISM.

The action taken by the British Medical Association at the last annual meeting with regard to hypnotism, which resulted in the appointment of a Committee of Inquiry,

will be strengthened by the report of the Standing Committee on Hypnotism appointed by the Medico Legal Society of New York, which had just been submitted. The report is not lengthy, but it is very much to the point. It states that "the number of reputable investigators increases, and that taken out of the hands of those whose aims and methods cast discredit on it, hypnotism is studied by members of the learned professions vitally related as it is to the interests of which they are the natural custodians." Whilst we hold to the opinion that hypnotism should only be practiced by qualified medical men, we cannot deny there are medico-legal questions connected with the study of the subject which, on further investigation, may be found worthy of attention. Before, however, going so far as the Committee of the Medico-Legal Society of New York, and countenancing the study of this subject by "members of each of the learned professions," we should be satisfied that the medico-psychological aspect of hypnosis is clearly defined and understood. The moral and legal relationships of hypnosis, which the medical profession has now begun to regard as a physiological and not a pathological state, can only be studied with advantage by the learned professions after it has been thoroughly investigated and given the place to which it may be found to be entitled by those competent to undertake such a purely medical inquiry.

Briefly, the conclusions which the Standing Committee arrive at are: That hypnosis, or artificial trance sleep, is a subjective phenomenon, that it is not in itself a disease. Neurotic conditions predispose to the trance sleep, but the strongest minds have been entranced. Hypnosis is recognized in three stages—lethargy, somnambulism, catalepsy. It has been serviceable in medical and surgical practice as a therapeutic agent, and in some cases as a safe anæsthetic. The last proposition, that "the illusory impressions created by hypnosis may be made to dominate and tyrannize the subsequent actions of the subject" is far from being established. We have not yet sufficient proof that post-hypnotic suggestion has led to actual crime, or that "illusory impressions" (hallucination?) have been either lasting or post-hypnotic. The more medical men study this interesting and possibly valuable agent as a means of combating disease, the stronger will the desire of the profession become to see it taken out of the hands of showmen. Nothing can be more degrading to the medical profession than to see these would-be doctors posing in public and filling their pockets by exhibitions of the power of hypnotism before lay audiences, and to see them supported and patronized by medical men as stated by one of our correspondents in last week's issue.—*British Medical Journal*.

FROM BERLIN.

At last Wednesday's meeting of the Berliner Medizinische Gesellschaft, the discussion on Fraenkel's address, the longest and perhaps the most important discussion on record in the annals of the society, came to an end. Professor Fraenkel, in replying, said: "I am of opinion that tuberculin exercises a direct influence on those parts of the body where tubercle bacilli exist,

and where they have caused changes to take place, and that this influence consists in a corrosive action with supervening necrosis. Thus I uphold my opinion that tuberculin is a specific for tuberculosis. If this be so, whence comes it that its therapeutic action is so much called in question? I think the answer is, because tuberculin does not affect the tubercle bacilli, and 2 because it has some untoward by-effects." He carefully weighed the pros and cons of the tuberculin treatment, such as his own experience had made known to him, and said that though fully alive to the possible dangers of the injections, he had found the curative effect in many cases so marked, so much greater than he had yet observed to follow any other therapeutic method, that in his opinion the physician, after having carefully and conscientiously selected suitable cases, must calmly face the danger in the same way as the surgeon does day after day. At the close of his remarks Professor Fraenkel referred to Professor Liebreich's new remedy, with which he had obtained surprisingly successful results in cases of tuberculosis of the larynx.

The Verein für innere Medizin has opened a discussion on Koch's tuberculin. The introductory address fell to Dr. Thörner, who reported most favorable experiences with the lymph, adding that, in his experience, the dangerous by-effects had been quite exceptional.

The official regulations as to the sale of tuberculin have appeared. The chemists are to obtain their supply from Dr. Libbertz, who will continue to prepare the lymph under the supervision of Professor Koch. It will be sold in sealed bottles containing from 1 to 5 cubic centimetres, and marked with the date of preparation. The chemists are to use the same precautions as with poison, and only to sell it in the original bottles and upon the written prescription of medical men. A special book is to be kept for the entry of sales, etc., and in each case the quantity sold, the date of preparation, of purchase, and of sale, and the name of the physician prescribing it must be noted. Six months after preparation the lymph may no longer be sold. Bottles six months old should be returned to Dr. Libbertz, who will exchange them for new ones without extra charge. The price has been fixed at 6 marks 6s. for a cubic centimetre, and 23 marks (£1 5s.) for 5 cubic centimetres.—Correspondence *British Medical Journal*.

INFECTION FROM MILK.

In the *Glasgow Medical Journal* for October appears an account of an epidemic of erysipelas and sore throat, occurring among families supplied with milk from a certain farm. The most striking symptom was an intense inflammation of the fauces, resembling erysipelas of the mucous membrane, with swelling of the glands of the neck, and in some cases suppuration. In some, true erysipelas of the skin developed. The temperatures ranged from 102° to 103° during the first few days of an attack. Convalescence was attended by extreme prostration. No bacterial examination was made, but a clear connection was traced between the milk and the epidemic.

PRACTICAL NOTES.

CONVULSIONS OF TEETHING.

- R. Chloral hydrat. gr. xv.
Potass. bromid., $\bar{5}$ j.
Syrup simplic., f $\bar{5}$ v.
Aq. destillat., f $\bar{5}$ j. \mathfrak{m}
S. Teaspoonful every three hours.—*Kinder-Arzt*.

PRURIGO.

The following prescription is useful in the treatment of prurigo:

- R. Resorcin. gr. xxxv.
Sulphur præcipitat., $\bar{5}$ v.
Acid. carbolic.
Acid. salicylic. $\bar{a}\bar{a}$ gr. vij.
Chloral. gr. xx.
Vaseline, $\bar{5}$ iss. \mathfrak{m}
Sig. Use externally.
—*La Semaine Médicale*.

OINTMENT FOR HÆMORRHOIDS.

Audhoui recommends, in *L'Union Médicale*, the following ointment for hæmorrhoids:

- R. Extract of belladonna, 15 grains.
Extract of thebaia, 15 grains.
Antipyrine, 45 grains.
Mercury ointment, 2½ drachms.
Simple cerate, 1 ounce.

—This is to be made into an ointment and applied to the inflamed hæmorrhoids. Rectal injections of warm water are to be employed if constipation is present.—*Medical News*.

INHALATIONS FOR OZENA.

Moire recommends the following to be used as a fumigation in the treatment of fetid nasal catarrh:

- R. Camphor, 1½ drachms.
Tincture of iodine, 3 drachms.
Iodide of potassium, 30 grains.
Tar, 3½ drachms.
Ninety-per-cent. alcohol, 3 ounces.
Water, 6 ounces.

Place this solution on a water-bath and inhale the fumes for two or three minutes, after which the nasal chambers should be washed out with a spray of 1-to-100 of carbolized water.—*Medical News*.

CONSTIPATION IN WOMEN.

- R. Citrate of iron and ammonium, grs. 31.
Fl. ext. cascara sagrada, m 32.
Saccharin, grs. 8.
Water, $\bar{5}$ iss.
M. Sig. A half teaspoonful three times daily before meals.

—*Medical News*.

IODIDE OF IRON IN LEAD POISONING.

It is stated by M. Lavrand, in a Lille medical

journal, that he has found iodide of iron, in the form of pills, as prescribed in the French Codex, very efficacious in treating the lead poisoning which occurs amongst workmen employed in white-lead manufactories. Sometimes he gives the iodide of iron by itself, at others he combines with it phosphide of zinc. Under this treatment workmen who had already commenced to show signs of lead poisoning were enabled to continue their occupation; their general health also improved, and the amount of hæmoglobin increased.

GONORRHOEA.

Thomas R. Neilson states that the plan of internal treatment which he has pursued for so many years past, consists, first, during the earlier stages of the disease in the administration of an alkaline sedative mixture, with the purpose of alleviating the scalding caused by urination, the tendency to frequent micturition and to chordee. The standard formula in his dispensary practice has been:

- R. Potass. acetat., $\bar{5}$ iij- $\bar{5}$ ss.
Potass. bromid., $\bar{5}$ jss.
Acid. boric., $\bar{5}$ iij.
Tinct. belladon., \mathfrak{m} xxx.
Liq. potass. citrat., $\bar{5}$ viij. \mathfrak{m} .

Sig.—A teaspoonful in water every three or four hours.

Secondly, as soon as the symptoms are in a measure relieved, the administration of either oleoresin of cubebs and balsam copaiba in capsule, or of cubebs alone in powder, in teaspoonful doses, or finally, where chordee is troublesome, a combination of two parts by weight of powdered cubebs and one part of bromide of potassium, given in the same doses, and from three to four times daily.—*Univ. Med. Magazine*.

TREATMENT OF SYPHILITIC ULCERATIONS.

Plumert gives the following applications for ulcers of syphilitic origin:

- R. Mercury salicylate, gr. xv.
Potassium carbonate, gr. xv.
Distilled water, $\bar{5}$ vj. \mathfrak{m} .

Dissolve. Sig.—Wet compresses with this solution and apply to the ulcerations.

If an ointment is preferred, recurrence may be had to the following:

- R. Mercury salicylate, gr. xvj.
Vaseline, $\bar{5}$ j.
 \mathfrak{m} . and make a pomade.

—*Bacteriological World*.

IRRITABLE BLADDER.

- R. Potassium citrate, $\bar{5}$ iv.
Fluid ext. triticum repens.
Tinct. of hyoscyamus, $\bar{a}\bar{a}$ $\bar{5}$ j.
Fluid ext. of buchu, $\bar{5}$ ss.
Water, sufficient to make $\bar{5}$ iij.

M. Sig. One teaspoonful in a wineglassful of water, three or four times daily.

—*Med. Summary*.

SOCIETY PROCEEDINGS.

Gynecological Society of Boston.

216th Regular Meeting.

The Gynecological Society of Boston met at No. 19 Boylston Place on Thursday, Nov. 13, 1890, at 4 o'clock P.M., with the President, W. SYMINGTON BROWN, M.D., in the Chair.

DR. FRANK L. BURT read a paper entitled

INTRA-UTERINE DISEASES—THEIR DIAGNOSIS
AND TREATMENT.

The reader placed the diseases to be considered under three groups, viz.:

First, the benign.

Second, the intermediate.

Third, the malignant.

The benign growths mentioned were, endometritis, erosions, areolar hyperplasia, submucous fibroids, uterine polypi, cystic degenerations and retained secundines. The intermediate were adenoma. The malignant were carcinoma and sarcoma.

Endometritis was treated at greater length because of its being a complication of the other diseases and a disease of itself. In case we find some tenderness about the uterus, likely also some enlargement, and we notice sticky mucus or a purulent discharge coming from the os, we can make the diagnosis of endometritis; provided we can prove that pus, if present, does not come from the tube. Division is made into cervical and corporeal endometritis, and it is generally believed that the cervical variety is much more common than the corporeal, although the causes are the same. Of all the cases which the reader has been called upon to operate, he has found that whatever the symptoms and whatever the kind of discharge, the whole portion of the endometrium has been more or less diseased.

For treatment he advises local applications of caustics, or the use of galvanism or thorough curetting. Local congestion should be relieved and proper constitutional treatment adopted. The method used would depend upon the complications in the case.

Polypi, or retained secundines, should be removed entire, and a local application of something like iodized phenol made to the surface. If we have uterine hæmorrhage, whether it be from the presence of fibroid or other causes, a thorough curetting is usually of great service. In many of these cases galvanism also is of decided advantage, many statements to the contrary notwithstanding.

Laparotomy should be advised in many of these cases of fibroids with severe hæmorrhage, and in some cases for severe pain, but the reader does not feel like condemning all these patients to abdominal surgery, because many of those who

have objected to surgery have been entirely relieved by local treatment; and he has also records of a large number of patients who have been urged to have the organs removed for tumor or hæmorrhage, who had been completely cured by galvanism alone.

If there was subinvolution or areolar hyperplasia, a course of chlorides was recommended for internal medication, while locally curetting and galvanism were advised. An old view that areolar hyperplasia is incurable must be revised to-day; for those cases are to be considered as perfectly curable by modern surgery.

In speaking of adenoma, a growth which may be benign for a long period, but which has a tendency to take on malignancy, the reader advised curetting with suitable applications as long as they might be considered serviceable, or as long as no malignancy showed itself. When such a change became apparent, the proper method to pursue was vaginal hysterectomy. This class of cases would, without doubt, furnish the greatest number of cures following this operation.

In the consideration of malignant diseases of the uterus the subject of diagnosis was recognized as of great importance, and it was thought that too much care cannot be given to all cases in which there is any possibility of malignant disease, because so many cases, unrecognized at first when curable, are allowed to go on without suitable operative treatment, till they were past all hope of anything more than temporary relief. Many such cases come to every surgeon.

It is perfectly evident that the disease must be discovered while it is yet confined entirely to the uterus, or else no treatment can cure. All internal medication and local application have failed in the hands of the reader. If the disease is confined to the cervix, where it originated, an amputation of the cervix will be sufficient to cure some cases, as shown by records of some years standing. If the disease is located at the fundus, no method will be of service except the entire removal by vaginal hysterectomy. This operation should not be performed in case the disease passes beyond the uterus. When we find a patient suffering from pain or hæmorrhage, and find that the disease has progressed so far that removal is impossible, we should still subject the patient to a thorough curetting for a complete removal of the sloughing tissue, after which caustic or cautery should be thoroughly applied. This treatment is often extremely satisfactory. The patient for the time recovers entirely from the foul discharges, hæmorrhage and pain. The relief at times is very great, and life, besides being made more comfortable, may be greatly prolonged.

DR. C. W. STEVENS said that he is very much interested in this subject. In regard to the manner of applying liquid medicament to the endometrium, he is accustomed to use a hard rubber

Eustachian catheter, to which a small rubber ball is attached, by means of which an injection of five to ten minims may be made. In a few cases there may be slight pain for five to ten minutes after the injection is thus made. This probably is a mild uterine colic. Dr. S. takes pains to be sure that the injected fluid flows out again, and hence he prepares a pad in the vagina to receive it. He places his best reliance, however, in ennetting to cure discharge of purulent or even mucus character when in excessive quantity. After he has curetted he applies the instrument devised by Dr. Outerbridge for the cure of sterility, which was originally made one and one-half inches long. It is self-retaining, and permits free drainage. When he makes an intra-uterine application of galvanism, he uses externally a large pad of spongio-piline, protected with gauze, which takes the place of the water apparatus and is especially useful when high currents are employed.

DR. C. E. PRIOR said that he rarely sees a case of endometritis which does not yield to the application of Squibbs' crude carbolic acid, and he believes if this does not produce the desired effect, that something else is at fault, after removal of which the endometrium gets well. He once had an unfortunate experience with creolin. Dr. Church mentioned that patients taste iodoform who have had it applied locally in the uterus and vagina.

DR. MARY E. BATES suggested that she should never think of curing endometritis without the use of hot water at a temperature of 118° to 120° F., in addition to other treatment.

DR. PRIOR agrees with this statement, and if only one method of treatment could be adopted, he would use the hot water.

DR. THOMAS P. JEFFERSON stated that he believed in the importance of drainage after the operation of ennetting, and he thinks that something should be left in the os that will allow the debris to come out easily. He also has used the Outerbridge instrument with success, and has also had good results by the insertion of gauze, which may be left for a day or two. Care should be taken lest the os closes and shuts the gauze in. He thinks there is more reason to be afraid of the intra-uterine application of caustics, etc., than of electricity.

DR. C. A. EASTMAN said that in cases of corporeal endometritis he finds the disease in patches, and he is accustomed to use the sharp curette, which should be used until the grating sound is heard.

DR. HENRY O. MARCY said that this is an old subject but it is one which is always interesting. What is endometritis? A name merely. Our opinions have lately changed in regard to all inflammations. What makes the inflammation in this case? The glandular apparatus is diseased by means of foreign material, viz.: microorgan-

isms, and all of the medicines which have been recommended in the line of treatment are anti-septics of greater or less value. The vagina affords most excellent conditions for the growth of microorganisms. In these cases the circulation and hence nutrition is also at fault. The cause should first be sought before attempting a cure.

Strong applications are too often introduced into the uterus, when such are used at all it should only be with extreme care. The operation of ennetting should not be thought lightly of. It should be done thoroughly if at all and with all the care of any surgical operation. Even after a thorough ennetting all of the glands are not destroyed. Ordinary menstruation may be said to be nature's effort to clean house each month. The glands are removed and they grow again. Dr. Marcy protests against doing the operation of ennetting with cocaine for an anæsthetic since when so done it can never be sure or safe. He does not generally use anything for drainage after ennetting, but if for any reason he wishes it, he prefers a small rubber tube. He does not as a rule make applications to the interior of the uterus, and prefers iodoform when he needs anything. He has never had occasion to regret the use of iodoform although the patients sometimes have the taste of the drug after it has been applied. He believes that the poisoning, when it occurs, is due to iodine and not iodoform.

St. Louis Medical Society.

Stated Meeting February 21, 1891.

THE PRESIDENT, L. BREMER, M.D., IN THE CHAIR.

[Abstracted for THE JOURNAL.]

TYPHOID BACILLUS.

DR. A. GREEN read a quotation from Koch relative to the difficulty of determining the species of bacilli—and particularly the typhoid bacilli—inasmuch as there are as yet no distinguishing or constant marks which positively indicate the specific typhoid germ.

DR. BREMER spoke of the method of separating and differentiating various bacilli in Koch's laboratory, and also referred to the way in which the cultivations were made.

DR. GREEN believed that the bacillus of typhoid fever was not present during the earlier stages of the disease, not being shown in the feces under a week or ten days.

DR. BREMER referred to the difficulty of diagnosing typhoid in its early stages, and even throughout the entire course of its manifestation. He also spoke of the difficulty of the comparative study of contagious diseases on the lower animals, inasmuch as the disease, in a characteristic form, cannot there be produced.

ENCYSTED HYDROCELE OF THE CORD.

DR. BROKAW presented a specimen which was of interest more directly from the mistake in diagnosis which it had caused. It had been taken for a hernia, and had been treated as such heroically, and for a considerable time.

TUBO OVARIAN DISEASE.

Another specimen having much interest was also presented by Dr. Brokaw. The patient, 36 years of age, had suffered greatly for a long time. Childbirth occurred seven years previously, and for the last fourteen months the patient had been bedridden. The case had been variously diagnosed, and treated accordingly. At the operation very extensive adhesions were found, and a large, far-reaching abscess, involving and surrounding the larger blood-vessels of the region. The patient was extremely emaciated, and died on the fifth day after the operation.

MYXO SARCOMA OF THE KIDNEY.

A third case was that occurring in a child 3 years and 8 months of age. This is the second youngest child operated upon for this peculiar disease. Altogether twenty-nine previous cases have been reported in young children. In this case the tumor had developed very rapidly. Operation took place in November, but the child had a metastasis involving the liver and succumbed two months ago.

INTRA-CRANIAL TUMOR.

DR. N. S. CARSON rehearsed the history of a well-marked case of cerebral tumor involving the arm-centre first, but afterwards extending. The operation of trephining was performed, and patient made a good recovery until the eighth day when death occurred, the immediate cause of which was unknown. The case progressed very favorably in every way until the sudden onset of a state of alarm in the patient, which preceded the fatal termination but a short time.

DR. ATWOOD gave a word picture of two cases occurring in asylum practice, where the autopsy revealed the presence of cerebral tumors. In neither case could the diagnosis be positively made during life, nor a correct localization offered.

DR. BREMER believed that death happened, in the case reported by Dr. Carson, from the sudden relief of the pressure which had maintained from the tumor. This result obtained, whatever the operative dexterity had been on the part of the surgeon, and therefore reflected nothing against the surgeon's skill. In this case the tumor was large, and its removal was attended with considerable hemorrhage. Subsequent capillary hemorrhage took place, notwithstanding the presence of the gauze, and the general evidences of favorable progress, and finally death came from an œdema of the cerebral structures.

A general discussion followed touching the influences of coarse cerebral lesions, and the effects of brain pressure.

New York Academy of Medicine.

Section on Orthopedic Surgery.

SAMUEL KETCH, M.D., CHAIRMAN.

President of the Section.

CONGENITAL DOUBLE EQUINO-VARUS.

DR. CHARLES N. DIXON JONES reported a case in which ordinary, and other, methods had failed, necessitating, finally, the removal of both tarsi, with good results.

AGGRAVATED FLAT-FOOT.

DR. JONES reported a case where the inner side of the right foot rested, in its whole length, on the ground. Resection of the astragalo-scapoid articulation was made with good result.

TUBERCULAR OSTITIS OF THE HIP-JOINT.

TWOCASES of this disease were also offered by DR. JONES. In the first case there was high temperature, and the operation of resection liberated several ounces of pus. The temperature at once dropped, and there was a good recovery, not requiring apparatus, and with but one inch of shortening. In the second case the child was three years old and had never walked. There was a fluctuating swelling over the joint, together with the other symptoms of tubercular coxitis. A similar operation to that on the first case was done, and the recovery was rapid and uninterrupted.

DR. V. P. GIBNEY, in discussing the cases, said that in the first case the result was probably due to poliomyelitis, the anterior and posterior tibial muscles being mostly affected; and that in the effort to bring down the heel the flatness had been produced. He thought that a still further improvement could be produced by division of the tendo Achillis.

DR. ROYAL WHITMAN considered the result obtained in the case of the flat-foot a good one, but he withheld his approval from this class of operations. He felt that as good a result could be obtained by over-correction under ether, together with subsequent attention and exercise.

DR. A. B. JUDSON remarked that the occurrence of flat-foot as a result of infantile paralysis was rather unusual.

DR. R. H. SAYRE did not agree with Dr. Judson that equino-valgus was rare after poliomyelitis when the anterior tibial muscle happened to be the chief one involved. As to other points he did not believe there was any such thing as a relapsed club-foot; such cases were simply instances of imperfect cures, in which the patients had been unable to voluntarily retain the foot in

its normal position. He considered that Dr. Jones' excision of the hip-joint a very excellent piece of work, and believed it was much better than attempting to produce ankylosis.

HYDRARTHROSIS.

THE CHAIRMAN presented a case that he had first seen in 1887. Patient fifteen years of age. No history of rheumatism or joint disease, but there is phthisis on the maternal side. Two years before the right knee became swollen, and later the ankles and the left knee. General health is good, and there is no known cause for the trouble. Examination showed a large, doughy swelling of the knee; no pain; movements of the joint only limited by the effusion, and then only in extreme flexion. No elevation of the temperature. An exploratory puncture showed a clear, syrupy fluid. Treatment was first by plaster bandages, and afterwards by elastic compression, counter-irritation, and systematic massage of the joints. The progress of the case was at first slow, but afterwards became more rapid, until now there is very decided improvement.

DR. GIBNEY remarked that the case was interesting, both on account of its comparative rarity, and the excellent result which had been obtained.

DR. A. M. PHELPS had been accustomed in these cases of effusion into the joints, to open the joint and wash it out with a 1-1200 solution of bichloride. He believed it shortened the period of treatment; was a safe practice; and gave equally good results with the more common method. In dispensary practice his cases had been discharged in three months. Tubercular joints were not necessarily purulent. He had examined many microscopically, and while frequently finding the tubercle bacilli, yet there was no suppuration.

THE CHAIRMAN in closing the discussion, said that in private practice the consent to an operation, when there was such slight disability, could not easily be obtained; and furthermore he thought the operation somewhat dangerous in itself and liable to result, in a tuberculous case, in a general infection of the system.

RHEUMATOID ARTHRITIS.

THE CHAIRMAN also presented a man, thirty-six years of age, and with good family history. Had rheumatism when ten and fourteen years of age, and a third severe attack about ten years ago, which involved only the right ankle. Two-and-a-half years ago was exposed to damp and cold for a number of hours at night, which was followed by pain in the left hip, thence to the side of the leg and knee, and across the back to the right hip. After that the joints became stiff, though with only a feeling of soreness on motion. Now there was but little motion in both hips, yet the arms and hands were quite free. Has been

examined under ether, when the movements were somewhat increased.

DR. R. H. SAYRE said that the appropriate treatment was indicated by the movements made. Slight daily movements of the joints should be undertaken while the patient was immersed in a bath having a temperature of 110-115 degrees. Massage was more successful in this way. When the joints are inflamed and tender massage may intensify the inflammation so as to cause ankylosis, but in this case there had been absence of pain for a long time.

DR. GIBNEY approved of these suggestions.

THE CHAIRMAN, in closing the discussion, said that he had seen a number of these cases, and his experience had been unfortunate. The case should be classified as rheumatoid arthritis, which disease terminates in ankylosis. There might be temporary amelioration. He believed that massage and baths at the Hot Springs the best treatment.

THE IMPORTANCE OF THOROUGH EXAMINATION IN SUSPECTED POTTS' DISEASE.

DR. R. H. SAYRE read a paper having this title. He said that although in childhood the signs of Potts' disease are usually so marked as not to be confounded with other troubles, in adults, especially in females, there are times when the diagnosis is not clear. In some cases of uterine displacement and ovarian disease, the reflex pains, the position and gait, may simulate Pott's disease so closely as to be mistaken for it by competent observers.

A number of cases were cited illustrating the similarity of symptoms, and the errors made in treating the cases as Pott's disease; and where uterine replacement by a pessary or Alexander's operation, together with faradism and general treatment, produced a cure.

In conclusion the writer said that the description of these cases showed that the mistakes in diagnosis had been made by men of large experience, and he therefore thought it worth while to call attention to the fact that reflex pains from pelvic irritation might easily lead one astray in considering cases of supposed Pott's disease.

PATHOLOGICAL DISLOCATION OF THE HIP.

DR. W. R. TOWNSEND presented a specimen of this condition which had been removed from an Italian girl. The head of the femur was deeply eroded and was dislocated on to the dorsum ilii. There was a marked erosion of the pelvic bones, but no perforation of the pelvis.

ACUTE INFANTILE ARTHRITIS.

DR. TOWNSEND also presented a specimen showing acute arthritis in an infant 11 months old.

DR. JUDSON said that the specimen illustrating pathological dislocation of the hip recalled a discussion which took place a few years ago on the

question of the possibility of this dislocation. Dr. March, of Albany, argued that Dupuytren, Astley Cooper, C. Bell, Brodie, Liston, Ferguson, Miller, Gibson, Carnochan, and a host of other authorities were wrong in considering spontaneous dislocation in hip disease as a frequent occurrence. He declared that, as purely the result of morbid action unaided by superficial violence, it seldom, or never, took place. He visited forty pathological museums in all parts of the world, and failed to find evidences of this lesion. His forcible article in the "Transactions of the American Medical Association, 1853," excited great opposition, and Dr. Hayward, of Boston, in his Surgical Reports, 1855, said it would require more specimens than would fill forty, or forty thousand museums to convince him that a certain specimen, which he described, was not the result of spontaneous dislocation.

Before this discussion, spontaneous dislocation was supposed to be a very common incident of hip disease, in spite of the doubts expressed by Baron Larrey, and the statement by Wickham, in 1833, that it is of very rare occurrence. That dislocation is very often simulated when not really present, is not generally conceded.

Dr. GIBNEY showed a specimen to the Pathological Society in 1877, in which dislocation was simulated by an appearance due to the altered direction of the neck of the femur. But that it sometimes does occur, is clear enough from the fine specimen in Dr. Townsend's hands. There is another pathological dislocation of the hip that is worth considering from an orthopaedic standpoint, *i. e.*, that thought to be produced by distention of the capsule in the synovitis following continued fevers, as set forth by Dr. Keen, in the fifth Toner Lecture in 1877. He had recently examined a convalescent from typhoid fever in whom there was great impairment of motion, and a distended capsule. Ostitis was eliminated by the history of the case, and by the absence of atrophy and natal asymmetry. The patient was warned against undue disturbance of the joint, and recovered without dislocation, and without any special treatment. The subject is practically important because it is generally believed that serious joint diseases not infrequently have their origin in fevers.

Dr. Gibney said that he would like to know whether Dr. Townsend thought the child might have been saved if the head of the bone had been excised. A number of years ago Dr. Yale read a paper on excision of the hip, before the Surgical Society, and among other conclusions he stated, that the best antipyretic for septicaemia was excision of the hip.

Dr. TOWNSEND replied that there was marked septicaemia present at the time he had operated and drained the abscess, so that he doubted if the result would have been different had he excised

the head of the bone. He thought, however, that an earlier operation might have saved the child's life. He had recently seen in Bellevue Hospital a man suffering from aggravated septicaemia due to absorption cellulitis of the leg, who was so ill that it was feared he would die on the table during the amputation of the thigh; yet, instead of this, the amputation was followed by a very rapid improvement in his general condition.

DOMESTIC CORRESPONDENCE.

LETTER FROM NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

New York County Medical Association.—A Koch Institute for Consumptives.—Dr. Simon Baruch on the Koch Lymph Treatment.—Dr. J. Blake White's Treatment for Tuberculosis.—Sanitary Condition of the Public Schools.

At the February meeting of the New York County Medical Association the retiring President, Dr. George T. Harrison, on vacating the chair, delivered an eloquent address, in which he dwelt upon the value and the desirability of a more general study of the medical literature of the past. In his admirable inaugural address the President elect, Dr. S. B. Wylie McLeod, alluded to the great success of the Association during the past year, whether viewed from the standpoint of an increased membership and a well filled treasury, or from that of the value and amount of scientific work performed. In speaking of the future he urged the cultivation of the closest possible relations with the State and National Associations. "We are their representative," he said, "in this County of New York, and they are ours in that unity of effort and purpose which gives strength to our cause. If we should be feeders to them in membership, and they in certain cases should exercise a supervision over us, it would be a relation at once natural and calculated to secure the great ends of our respective formations. A desire for coöperation and a willingness on the part of a distinct majority to thus organize, should precede the plan, and until these are first secured, it is a dictate of wisdom to wait; for it often happens that we should not take the course which is ideally most effective, but that one which commands coöperation and assent."

At this meeting sixteen new members were received; thus bringing up the total membership of the County Association to about 600.

A "Koch Institute for Consumptives" has been opened in the lower part of the city, on the East Side, and it will doubtless serve the purpose of affording considerable free advertising for the physicians having the project in charge, and, for

the time at least, bring in handsome financial returns. It would not at all do for some of the profession here, however, to cry out against such gratuitous advertising, as quite a number of the shining lights in it received a good deal of this in the newspapers at the time of the introduction of and first experiments with the Koch lymph. Aside from any such considerations, however, the wisdom of establishing an institution for the special purpose of employing the Koch treatment would seem to be extremely problematical at the present time, when grave doubts are felt by many of the best observers as to whether the treatment may not, after all, be more injurious than beneficial. That it has not accomplished as much as was at first hoped for from it there can be no question, and the unsatisfactory results that have thus far been met with led Professor Francis Delafield lately to make the remark that we seemed to be still as much in the tentative stage of the treatment of phthisis as ever. The present feeling in Berlin in regard to the matter is shown by the letter of Dr. Ingals recently published in *THE JOURNAL*.

It is now some time since Frinkel, observing the fact that the tolerance of the Koch remedy disappeared if no injection were made for ten days, and that the patient then became as easily affected as by the original dose, drew the conclusion that in phthisis tolerance is established as soon as all tubercle is acted upon, and was led to explain the return of the original susceptibility by the hypothesis that the patient had again infected himself with tubercle from the necrosed tissue lying in the lung, and that the reaction again appeared from a minimum dose because the case was once more a tuberculous one. If this explanation is correct—and the autopsies made by Virchow would seem to afford some corroboration of this, or at least to indicate that in certain instances the effect of the lymph treatment is apparently to disseminate the tubercle bacilli in the system—the difficulties in the way of success with the method would seem to be very great, if not altogether insurmountable.

In this city there have, of course, occurred some deaths in the patients treated with the Koch lymph, and it would certainly have been very remarkable if, among so many cases of phthisis, this had not been the case. In commenting on these deaths Dr. Simon Baruch, who at an early date began experimenting with the new treatment at the Montefiore Home for Chronic Invalids, writes as follows: "The public may easily be deceived by reports of death from lymph, because these cases happened to die while under the lymph treatment; but the experienced physician knows but too well how fallacious such a conclusion is in a disease which furnishes so large a percentage of the world's death rate. From an experience with over thirty cases of lymph treatment the

writer is led to the conclusion that, although the lymph has an undoubted elective affinity for tuberculous tissue, and produces decided local reactions, as Koch has stated, not one case has, after six weeks' experience, offered him the slightest evidence of a curative tendency. Nevertheless, he does not despair, because much time is required for the processes which Koch has delineated as probable in throwing off the diseased structures." On the whole, therefore, the establishment of a special "Koch Institute" at the present time would seem to be somewhat premature.

The most recent treatment for tuberculosis that has been advanced is that advocated by Dr. J. Blake White in a paper read before the Section on Practice of the New York Academy of Medicine. In addition to such general measures as are generally agreed upon by the profession, he employs hypodermically the chloride of gold and the iodide of manganese, given in a 1 per cent. solution of carbolic acid. The preparations of gold, he claims, have been too long neglected by the profession, though their value has been recognized from time to time by some of the highest authorities. Thus, Roberts Bartholow extols their efficacy in cancer, scrofula, syphilis and chronic Bright's disease, and at the same time he advances the important observation that they are singularly apt to undergo decomposition in the alimentary canal; a fact which may explain the inefficacy of the remedy when used internally, and which also offers the strongest reason for its hypodermic use. Under any circumstances, however, Dr. White believes that in phthisis the hypodermic method is the only proper one to use for medication, as the overtaxed digestive system has already more than it can attend to in disposing of the food taken into the body. He combines manganese with the gold for the reason that this drug has been found to have so excellent an effect in improving the character of the blood and increasing the tone of the general condition.

The minimum dose of the fluid employed is one drop, and this should always be given as the initial injection. The remedy appears to produce a reaction in the system very closely resembling that caused by the Koch lymph. Afterwards, it is claimed, there is increase in the appetite, followed by a marked improvement in the general nutrition, and later by an amelioration of the characteristic phthisical signs. In three illustrative cases narrated by Dr. White, which have been under treatment since December, the results, as far as they have gone, are certainly very encouraging. In one of them the body weight has increased nearly eight pounds, and in another the amount of expectoration has diminished from fourteen to two ounces in the twenty-four hours. These patients are in the wards of Charity Hospital, Blackwell's Island, and have been seen by

quite a number of other physicians. As to whether any permanent beneficial results will ensue it is, of course, entirely too soon to form any opinion. In addition to phthisis, Dr. White states that he has found the hypodermic use of these salts of gold and manganese very efficacious in the chronic glandular enlargements and sinuous abscesses of scrofula, in obstinate chronic skin affections, especially of a leprosy character, in chronic Bright's disease, and in persistent anæmia and the cachexias due to syphilis and scrofula.

The sanitary condition of our public schools has of late received a good deal of attention on the part of the medical profession. To this subject was devoted the principal part of the report of the Committee on Hygiene of the Medical Society of the County of New York at the last annual meeting of the Society, and at a recent meeting of the Section on Public Health of the New York Academy of Medicine, Dr. Henry D. Chapin, who industriously collected the data on which that report was based, read an additional paper on the same subject. He said that of the thirty-eight separate primary schools and eighty-one primary departments in grammar schools he had investigated eighteen of those which were known to be most defective, and that in ten of these he had found a condition of affairs that was simply disgraceful. His description of one of the schools on Chrystie street, in the midst of a crowded tenement-house population, which may be taken as an example, was as follows:

"In it there are over one thousand children in the primary department, which is housed in three buildings occupying the lower part of the grammar school building at No. 60, an old rookery, formerly a tenement house, and a factory on Hester street that has lately been patched up for this service. The children attending this school come from the poorest families in this densely populated neighborhood, and it is evidently regarded in consonance with the fitness of things to give them the poorest and scantiest of accommodations. Although the school was visited on an exceptionally bright and sunny day, eleven of the crowded, stuffy rooms were lit by gas, which, with the poor ventilation, made the atmosphere almost unbearable. Even the main room was partially lighted by gas, the windows on the right opening into a narrow well, at the bottom of which are boys' water-closets. The classrooms in the tenement-house and factory have low ceilings, are generally poorly lighted, and are very badly ventilated. It is difficult to comprehend how teachers and scholars can remain for hours in the polluted air of these rooms, and not become ill. In the latter two buildings the stairways and passages are narrow and tortuous, and they might both prove a veritable fire-trap, especially as thin wooden partitions are used to sep-

arate many of the rooms. It would be absolutely impossible to empty these buildings speedily and safely in case of alarm. Several of the class-rooms have no desks. There is a small, dark playground in the basement. Altogether, this school contains a combination of unhygienic conditions that has probably been rarely equalled in a building devoted to such a purpose."

In speaking in general Dr. Chapin said: "The ventilation of the primary schools is dangerously defective, and the cubic air space allowed to each pupil is insufficient. In the three lower classes the prescribed allowance of space to each pupil is 70 cubic feet, and in the three higher grades, 80 feet; while in the four lower grades of the grammar classes the allowance is 90 feet, and in the four higher grades, 100 feet. The Board of Health requires that in tenement-houses the allowance shall be at least 400 cubic feet, and in some cases 600 cubic feet, to each person. 400 cubic feet are required for each lodger in the lodging-houses of this city. There is not a city in the country that requires such a small number of square feet and cubic feet per pupil as New York in its public schools. . . . The life conditions of thousands of poor children in tenement-houses are hard enough. It is the duty of the city to see to it that their bad environment is not continued in the schools. As children grow older, and growth is not so active, the system loses this susceptibility to noxious influences. In young children, however, where unhygienic conditions prevail, the constitution will surely be weakened and the effects particularly disastrous."

The Superintendent of School Buildings, who was present on this occasion, explained that the unfortunate condition of affairs referred to was due principally to the fact that the Board of Education was able to obtain from the city but a small proportion of the funds which were necessary to carry out its work properly. During the past four years, however, no less than twenty-seven new school buildings had been erected, in whose accommodations and appointments the medical profession would find nothing to criticize. In reply, Dr. Alexander, the Secretary of the Section, said that to the physicians of New York it made but little difference who was responsible for the evils existing in the schools, and that it was simply their duty to demonstrate these evils scientifically and incontrovertibly until public sentiment should demand their abolition.

It would appear, however, that New York is not the only place where school-houses are not all models of hygienic perfection. The Hudson County (N. J.) Board of Health recently declared one of the public schools of Jersey City to be in such a bad sanitary condition as to require the immediate attention of the city school authorities. A reasonable time having been allowed to pass, and nothing whatever having been done to im-

prove the premises, the Board of Health, at its last meeting, very properly ordered the school to be at once closed.

P. B. P.

NECROLOGY.

DR. STEPHENS G. COWDRY, Surgeon U. S. A., died in New York City Feb. 22, aged 52 years. He was a native of New Hampshire, and appointed from New York in 1868. He had been on sick furlough since last December, having left his post at Santa Fé at that time in order to consult with friends, medical and others, in the East, in the interests of his health. The cause of his death is assigned to heart-failure.

DR. JOHN A. MEAD, of Pearlington, Miss., died at the Hospital Hotel Dieu, New Orleans, La., on January 30, 1891. He was born in Portland, Me., July 16, 1842, educated at Harvard Medical School, Boston, and graduated June 30, 1869. He had been a sufferer from abscess of the liver, but finally succumbed to an attack of bronchial pneumonia. He was a member of the American Medical Association since 1885.

DR. FORREST W. BRAYTON.—The sad news is announced of the sudden death, in Cincinnati, of Dr. Forrest W. Brayton. In January, 1890, Dr. Brayton went to Toledo and associated himself with Dr. W. W. Jones, in the practice of medicine, and at once became a favorite with all with whom he came in contact. He was successful from the beginning, and had an extremely bright future before him. But sickness came, and some months ago he was obliged to give up his work. Since then he has been traveling, trying to regain his lost health, but without avail; death came and ended his career, so auspiciously begun.

Dr. Brayton was only 34 years of age, his home being in Carey, Ohio. He was a member of the Northwestern Ohio Medical Association, of which he was at one time Vice-President, and later Secretary. He was also a member of the Ohio State Medical Society, of the American Medical Association, of the American Microscopical Society, and of the Toledo Medical Association.

JOHN S. MESSERSMITH, Medical Director U. S. N., retired, died at Lancaster, Pa., Feb. 16, aged 81 years. He was commissioned by President Andrew Jackson in 1837, and served in Commodore Perry's first expedition to Japan, as well as during the Mexican and Civil wars. He was retired in 1872.

DR. MARIUS DUVAL, Medical Director of the U. S. Navy, with rank of Commodore, retired, died suddenly on February 21 at his home in Baltimore. He was nearly 73 years of age.

SPECIAL CORRESPONDENCE.

To the Editor:—It affords me much pleasure to inform you that our bill repealing the charter of the Medical and Surgical College of this State has been passed by the Legislature and approved by Governor Abbott. It is hardly necessary for me to say that this Board feels that it has, in the first year of its existence, done something towards the purification of the medical profession, not only in the State of New Jersey, but in its sister States.

WM. PERRY WATSON,

Sec'y State Board of Medical Examiners,
Jersey City, N. J., March 11, 1891.

Shall The Journal be Removed to Washington?

THE ACTION OF THE CHATTANOOGA MEDICAL SOCIETY.

At a regular meeting of the Chattanooga (Tenn.) Medical Society, March 6, 1891, the following resolution was passed, viz.:

WHEREAS, An effort will be made at the next meeting of the American Medical Association to move THE JOURNAL from Chicago to Washington, and

WHEREAS, We believe it to be for the best interests of the Journal to remain where it is: Therefore,

Resolved, That we urge all Tennessee delegates to vote for no change to be made in the home of THE JOURNAL.

FRED. B. STOPP, M.D., Sec'y.

THE ACTION OF THE WAYNE COUNTY MEDICAL SOCIETY.

At a regular meeting of the Wayne County (Ind.) Medical Society, held on the 12th inst., Dr. L. C. Johnson moved:

That it is the sense of this Society that the office of THE JOURNAL of the AMERICAN MEDICAL ASSOCIATION ought not to be removed from Chicago to Washington at this time, and that the delegates from this Society to the next meeting of the American Medical Association are hereby instructed to vote against such removal.

After full interchange of views of members on the subject the motion was unanimously adopted.

G. H. GRANT, M.D.,

Sec'y Wayne Co. Med. Society,
Richmond, Ind., March 13, 1891.

To the Editor:—I am most unalterably opposed to the proposed change.

It is very evident that the movement for the change from Chicago to Washington has had its origin in the minds of some, who are very reluctant to admit the fact which should be plainly apparent to all, that not only the centre of population but the financial and intellectual centres are surely moving westward. Nothing worthy the name of argument has as yet been advanced in favor of it, neither can there be, for there is none to offer.

Some of the reflections which have recently been cast upon the management of THE JOURNAL, and upon the character of its contents, have been, to say the very least, uncalled for and out of place. The profession as a whole is not only well pleased with THE JOURNAL, but is proud of it, and in my judgment with the best of reasons. I turn to my old volumes of the London *Lancet*, the *American Journal of Medical Sciences*, and others, and search in vain for anything so nearly representing and embodying advanced thought and progress in all departments of the profession.

No! Leave it where it is, in Chicago, the eighth wonder of the world, destined to be, within the lifetime of thousands now living, the greatest city upon the Continent. I would leave it in Chicago also because its great and growing success has already been achieved there, and that city is the home of many of its best and earliest friends, one in particular, whose name I need not mention. There are no end of arguments that could be

advanced against the change, but the facts have been so ably and unanswerably set forth by recent writers that I will not enlarge upon the theme.

There seems good reason to believe that, in many respects, the welfare of THE JOURNAL would be jeopardized by the consummation of the proposed change, and I have little fear that the small and obscure band of "kickers" can succeed in the consummation of this folly.

LUTHER BROWN, M.D.

Rockford, Iowa, March 3, 1891.

To the Editor:—In my opinion THE JOURNAL should remain where it is. It is centrally located and prosperous. Chicago bids fair to become one of the great centres of learning, generally and specially. Sooner or later, its great clinical advantages will go far toward helping to make it one of the, if not the centre of medical learning.

J. B. WALKER, M.D.

Effingham, Ill., February 26, 1891.

To the Editor:—Being a reader of THE JOURNAL and interested in the question of its removal from the old stand, I was curious enough to figure out the number of subscribers (members) in the principal Eastern cities as compared with those in the West, and I find Chicago leads them all.

The number of subscribers (members) in the Eastern cities is as follows: Philadelphia 109, Washington 52, New York 77, Baltimore 35, Brooklyn 25, and Boston 33, making a total of 301 copies distributed in six cities with a population of nearly two millions. In the Western cities: Chicago 171, Cincinnati 53, St. Louis 79, Louisville 24, Detroit 28, and Cleveland 20, making a total of 405 subscribers (members) in six cities of a population of about two and a half million. The Eastern States make the following showing: Pennsylvania 307, New York 234, Massachusetts 121, New Jersey 55, and Maryland 44, a total of 851 in a population of nearly sixteen millions. In the West: Illinois 406, Ohio 352, Indiana 275, Iowa 220, and Missouri 213, being a total of 1,486 subscribers (members) in a population of about fourteen millions. I take these from the list of members published in THE JOURNAL at the conclusion of the last volume.

So far as the advertisement department is concerned, New York and Chicago seem to be about equally divided. Washington, however, has only three advertisements, viz.: the Medical Department of the University of Georgetown, J. E. Ruebsam, and that of the Librarian of the Association. I have simply for curiosity found these figures, and they can be used by either party accordingly as they look at them.

READER.

Washington, D. C., March 6, 1891.

To the Editor:—I have read the arguments pro and con, anent the removal of THE JOURNAL. My vote is with Chicago, believing it to be the best interests of THE JOURNAL to remain where it is. Would it not be well to request every member of the Association to send a postal card with his vote, not later than April 4? I believe we are all interested enough to do this, and in this way it will not cost THE JOURNAL much to find out which side has the majority.

PHILIP DICKES, M.D.

Boundary, Ind., March 7, 1891.

To the Editor:—Please allow me to record my vote in favor of THE JOURNAL remaining in Chicago. "Let well enough alone!" A thousand reasons and arguments might be offered why it should remain in Chicago, while as many could be given against its removal. "Westward the star of Empire takes its course." Chicago is certainly a great medical centre, and perhaps the greatest railroad centre in the Union; her future is great, so that

there cannot be a foreboding of the future success of THE JOURNAL, for its removal to London is on a sound and enduring basis, while its editorial management has always been of the highest order. Its editorialials are liberal, progressive, broad and cosmopolitan. While its attitude has been conservative and judicious, it has assumed a high position for the advancement of the whole domain of medicine. The aim of THE JOURNAL has been of a high and lofty character in the exposition of the grand principles of the Code of Medical Ethics. It has also been a most potent factor in the effort to raise and elevate the standard of medical education. THE JOURNAL has been loyal to the masses of our noble profession, and in this it has been as free from the manifestation of a partisan spirit as the most liberal minded person could expect, and the profession will give their loyalty and support in return. By all means leave THE JOURNAL in Chicago.

H. H. MIDDLEKAMP, M.D.

Warrenton, Mo., March 5, 1891.

To the Editor:—Allow me, as a member of the American Medical Association since 1877, to enter my protest against the removal of THE JOURNAL to Washington. I fail to see any good reason for its removal.

H. ISAAC JONES, M.D., L.R.C.P.L.

118 Grant Ave., San Francisco, Cal., March 7, 1891.

To the Editor:—No! GEO. A. ZELLER, M.D.
Peoria, Ill., March 6, 1891.

To the Editor:—You may record my vote in favor of Chicago as the home of THE JOURNAL.

J. D. COLI, M.D.

Newbern, Tenn., March 6, 1891.

To the Editor:—It is a matter of no urgent importance to the readers of THE JOURNAL whether it be published in Chicago or in Washington, unless it can be proven that it can be made a better journal in Washington than it can in Chicago. The members of the Association estimate THE JOURNAL by its merits and hold the Editors and Publishers responsible for its character. It should be left with them to determine where it would be most convenient for them to do the work and do it best. When the National Government makes liberal appropriations for the establishing of a National Medical Institute, and makes provisions for professorships by which experimental research can be conducted; where hospitals, libraries, museums and other necessary helps are provided by the government, as is done in some other countries; then I say move to Washington.

J. W. HARVEY, M.D.

Indianapolis, Ind., March 10, 1891.

To the Editor:—Record my name in favor of removing THE JOURNAL to Washington. The official representative of the profession should keep as closely to the government as possible.

E. T. B. GODFREY, M.D.

Camden, N. J., March 10, 1891.

To the Editor:—The location is of much less interest than the character of THE JOURNAL. The members of Congress are very careful about their journal. It is a record of their doings. It is a photograph, so to speak, of each individual as well as the whole. A journal goes into history as the exponent of this or that body of men. Now, Sir, I submit that all this squabble about location, will not appear upon the page of history as reflecting a very bright halo of glory from the A. M. A. Therefore, I move the previous question. Let us have no more of it.

S. E. HAMPTON, M.D.

Milton, Ky., March 12, 1891.

To the Editor:—I cast my vote in favor of THE JOURNAL remaining in Chicago, the best place for it.

L. L. LEEDS, M.D.

Lincoln, Ill., March 13, 1891.

To the Editor:—In reference to the removal of THE JOURNAL to Washington, I have a high appreciation of the Eastern brethren and their journals, and their ability to conduct them. I have just as high an appreciation of the profession in the West, as I have of those in the East, and regard them equally competent to conduct THE JOURNAL as the former, and therefore object to the removal of THE JOURNAL from Chicago to Washington, as a needless and needless expense, besides the accompanying loss of talent which would follow.

J. W. CRAIG, M.D.

Mansfield, O., March 12, 1891.

To the Editor:—Dr. Comegys' letter in last week's JOURNAL was a most agreeable surprise to me. I feel that he has given a new interest to the subject, and made in reality a most convincing plea to have THE JOURNAL remain where it is. One or two more letters of this character would practically fix THE JOURNAL at Chicago for at least a generation to come.

While the text of his letter seems to favor a removal to Washington, the reasons he urges are the very strongest which have been published, showing the necessity of leaving THE JOURNAL where it is.

The charge of conservatism and want of aggressive spirit is the highest compliment he could pay to the present management. The unwillingness of the managers to select a highly competent editor to direct things, is equally flattering; the history of medical journalism shows that only through prudent conservatism, and with a non-aggressive spirit, can any journal hope to survive the perils of childhood. The sagacity of the managers is commendable who early recognized that highly competent editors were not on the market, but were products that had to be grown; also that the very laudable ambition to attain an exalted position, and become the leading journal in the country, was also a matter of growth hardly attainable in eight years—especially in view of the historical fact that for nearly half a century journals in Boston, New York, and Philadelphia have sought to attain this position, sustained by capital, enterprise, and very superior intelligence. Yet it is by no means clear that any one of these journals lead all the others, or have attained the exalted position of the great journal of the country.

It would appear to be of the nature of a miracle to expect a journal depending entirely on the good will of an association, and in the face of over a hundred rival journals, to become independent, and attain a degree of solidity and leadership that would command the Association, in eight years. It took over a quarter of a century of experience for the *British Medical Journal* to attain this, and many journals of longer experience sustained by large capital and shrewd management have not yet accomplished it.

It will be new to practical business men, that the consciousness of the National Capital is of so much importance in the life of a struggling journal. While this power in Chicago may not equal that of Washington, the value of this spirit entity would rank very low amongst business men. The same may be said of the social and political recognition possible at Washington. Experiments in the publication of journals have been going on for over half a century. Publishing houses, colleges, societies, men with capital, and ambitious physicians of all grades, have tried every conceivable plan to grow and build up a National journal. Change of location, consolidation, cheapness of rates, frantic appeals to the readers, selling out to advertisers, and yet all failed.

The same experiment is repeated to day, and if Washington offered the slightest possible advantage over Philadelphia or New York or Baltimore, shrewd men would occupy the field at once. If Washington could infuse new life in any journal, or make its success any more certain in the future, many well established journals would move into this field in a week. Over thirty journals are published within a day's ride of Washington, and not one of them have yet discovered that this city offers any possible inducement, or promise of success for the publication of a medical journal.

To practical men who know what medical journalism is, there is only one road to success, and that is along the line of prudent conservative management, with the least possible risk in any direction. The change to Washington is a risk, it is leaving a certainty for an uncertainty, and the hunt for an ideal editor will go on while the world lasts.

Dr. Comegys' letter comes like a flash light along the shore, telling us of the danger of a change to Washington and warning the members to look out for breakers.

A wild rocky beach strewn with wrecks of journals is in sight, and I ask in the light of the history of journalism in this country, what reasons have we to expect that the change of location and change of management will not end in a wreck on the same shore? Will THE JOURNAL escape the same fate which has befallen others?

There can be no doubt that Dr. Comegys was obscure as to names, and that the central idea of his letter was to have a good practical journal grow up where it is at present, and be an honor to the Association. If this is not clear another letter from Dr. Comegys will settle the difficulty at once.

T. D. CROTHERS, M.D.

Hartford, Conn., March 16, 1891.

To the Editor:—I am not in favor of the removal of THE JOURNAL from Chicago to Washington, because I feel confident that such a measure, if carried out, would be a rash one, and would prove to be a serious detriment to the future prosperity of THE JOURNAL. The permanent establishment of THE JOURNAL at Chicago, and the selection of Dr. Davis as its editor-in-chief, gave indications of a grand success in the development of medical knowledge and practice, and in the evolution of a journal that should be second to none in this country, if not in the whole civilized world, and of a journal that all fair-minded persons would regard as worthy of its distinguishing title, "Our National Medical Journal." That these anticipations have been largely met there can be no question. We have ample proof that THE JOURNAL has been extensively read, and the reports of cases have been gleaned, incorporated in other papers published not only in our own language, but also in the languages of other countries.

Some fault has been found because all the papers published have not been up to certain individual standards. In answer to this I need only say that the appearance of such articles in our journals is not so much the fault of the editorial staff as it is from the crudeness of many of the theories of the medical profession generally. The profession was not made for THE JOURNAL; THE JOURNAL is but a mere reflection of the methods of practice of the individual members composing the Association. Since the American Medical Association was founded, and more especially within the last decade, there have been organized many different associations composed of specialists. The peculiar standards of many of these have directed the attention of their members toward the preparation of papers in accordance with their own requirements, to be included in volumes of their own publication. Notwithstanding all these drawbacks, the American Medical Association has had the good fortune to be able to publish some as carefully prepared papers as were ever offered as contributions to associations of such special class.

Should we change our location of publishing to Wash-

ington, what guaranty would there be that our journal, which was not established, of course, for a clique, class, or for any special hospital staff, or for political incumbents, but rather to be a National journal, would be better enabled to eradicate the evils that have been charged against it, to say nothing of incurring the risk of sinking below the standard to which it has already attained? *We cannot afford to try the experiment.* The profession of Washington, though counting among its members several worthy and distinguished lights, is not specially famous for organizing and maintaining medical journalism. The city itself is not a great centre; it is too far east. It is true that Washington is our National Capital; it is also true that it is the *rendezvous* of a large class of politicians and office-holders who can only thrive by having their hands in range of the public purse. From such we should be forever divorced.

Something has been said relative to the Medical Library and the Museum at Washington. In regard to that argument, I fancy that the supposed advantages of such helps are more theoretical than practical. Their collections, for authors of larger works and for students of special study, will always prove, no doubt, to be of priceless value. For editors who are to keep abreast of the times, and who are to inspect and supervise papers for a weekly journal, I fail to see how these great collections can be of all-important service.

That Chicago is a good field and is abundantly able and ready to sustain a first-class journal, no one can deny. The city is of sufficient distance from Boston, New York, Philadelphia, etc., as not to interfere with those local centres. The location of Chicago has given the city a strong, healthy and marvellous growth. The medical profession of Chicago stands high. I have only to instance the reports and proceedings of her Gynecological Society to corroborate this statement. Its Transactions are the very models of what such a Society should present. Let us, then, retain our old base of operations, ever seeking to uphold the standard of *OUR JOURNAL*, for in so doing we are confident that we have a rich and brilliant future before us.

AUGUSTUS P. CLARKE, M.D.

Cambridge, Mass., March 8, 1891.

To the Editor:—It would seem from the number of opposing voices that the proposition to remove *THE JOURNAL* from Chicago to Washington is overwhelmingly snowed under. This, however, does not prove that the minority who favor the change is in the wrong. Between the hues of all these staunch advocates of Chicago a strong sectional bias is plainly visible. Whenever sectional prejudices are permitted to rule, then all hope of a judicial frame of mind is gone.

The geographical or population argument, which has been so strongly emphasized by nearly all who oppose the change, really has no place in this question.

The question is not a commercial or a financial one, much less is it a question of noses. All these would have great weight were a bank, a manufacturing or a packing establishment to be located, but in the selection of a suitable place for publishing a scientific journal they, in my opinion, ought not to enter.

It is simply a question of "the eternal fitness of things." *THE JOURNAL* is a representative sheet, the mouthpiece of the medical profession of the United States, and as such, it ought to have its home at the Capital of the Nation. It should not be associated or identified with the name of any town, city or section, however mighty it may be, save only, the Capital City of the whole country.

Of course, there are many other good reasons, why *THE JOURNAL* should be issued here. The fact might be cited, that Washington is fast becoming a centre of literary and scientific culture. Every year, men and women possessing attainments in these directions come from all parts of our land, and either settle here permanently, or

for a portion of the year. They find in the great Congressional Library, in the Smithsonian Institution, in the National Museum, and in the different departments, are untold wealth of materials suitable for their study and investigation. Men of all shades of political or religious opinions, inventors, people with various literary scientific bent are wont to visit the National Capital for an exchange of views or for recreation. While everything of this sort is centering and crystallizing in Washington, would you have the medical profession make for herself a capital elsewhere? London, Paris, and Berlin and other cities of Europe, is each the literary, scientific and medical, as well as, the political capital of its respective country; why should Washington be an exception in this respect?

I am fully aware that some men are so provincially inclined as to lose their appetite when away from home or from their accustomed place at table, or fail to relish the news of the day, unless dished up by their favorite newspaper, but it is to be hoped that these little peculiarities and prejudices will not be permitted to sway the judgment in selecting a permanent and suitable home for *THE JOURNAL*.

J. W. SHIPLEY, M.D.

Washington, D. C., March 16, 1891.

To the Editor:—Having looked the ground all over fairly and carefully I have come to the conclusion that there is no place better fitted for its publication than Chicago. There are many reasons why, but as they are familiar to all I will not rehearse any.

E. J. TIDD, M.D.

Clark, Pa., March 12, 1891.

To the Editor:—I vote to have *THE JOURNAL* remain at Chicago. I appreciate its weekly visits, and hope its era of prosperity will constantly increase.

J. A. HINES, M.D.

Van Wert, O., March 13, 1891.

To the Editor:—Why should we move *THE JOURNAL* to Washington? It is a great political centre and nothing more. We do not want *THE JOURNAL* entangled in the wire-pulling of medical politicians. *THE JOURNAL* is the expression of the American Medical Association, and not of self seekers in politics. Certainly the "original work" could not be improved by locating it at Washington. I do not know of much lasting original research coming from a political centre. The men in such places are usually too busy in self seeking to work very hard. By all means keep *THE JOURNAL* in Chicago.

JAMES T. JELKS, M.D.

Hot Springs, Ark., March 13, 1891.

MISCELLANY.

DR. HOSMER ALLEN JOHNSON.—The following resolutions were adopted by the Faculty of the Chicago Medical College at a meeting held on February 28, 1891:

Resolved, That in the death of Hosmer Allen Johnson, M.D., LL.D., the Chicago Medical College has lost the services of one of its founders and most active, able and eloquent teachers, the Northwestern University one of its wisest Trustees and Counsellors, the medical profession one of its most learned, honorable and influential members, and the community one who for nearly forty years has been an active, skilful and untiring benefactor to the suffering, alike in peace, in war, and in the midst of the direst of conflagrations.

Resolved, That to his bereaved family and friends we tender our most sincere and abiding sympathy, and the assurance that their temporal loss is his eternal gain.

Resolved, That the Secretary of the Faculty furnish a copy of the foregoing resolutions to the family of the deceased, and to the medical and other periodicals of this city.

*Official List of Changes in the Stations and Duties of Officers Serving
 in the Medical Department, U. S. Army, from March 7, 1891, to
 March 15, 1891.*

RETIREMENT.

Lieut. Col. Blencowe E. Fryer, Asst. Medical Purveyor, February
 14, 1891.

PROMOTIONS.

Major Charles R. Greenleaf, to be Lieut. Col. and Asst. Medical Pur-
 veyor, February 24, 1891.

Capt. Charles K. Winne, Asst. Surgeon, to be Major and surgeon,
 February 27, 1891.

Capt. Timothy E. Wilcox, Asst. Surgeon, to be Major and surgeon,
 February 24, 1891.

Capt. Fred. C. Ainsworth, Asst. Surgeon, to be Major and Surgeon,
 February 27, 1891.

Capt. Valery Hazard, Asst. Surgeon, to be Major and Surgeon, Feb-
 ruary 27, 1891.

By direction of the Secretary of War, a board of medical officers, to
 consist of Col. Edward P. Vulliam, Chief Medical Purveyor; Lieut.
 Col. Dallas Bache, Surgeon; Major Alfred C. Girard, Surgeon; and
 Capt. Charles M. Gandy, Asst. Surgeon, is constituted to meet in
 New York City, on March 16, 1891, or as soon thereafter as practi-
 cable, for the examination of candidates for admission into the
 Medical Corps of the Army, and such other business as the Sur-
 geon-General may desire to bring before it. Par. 18, S. O. 52, A.
 G. O., Washington, March 7, 1891.

Capt. James A. Finley, Asst. Surgeon, having been found by an
 Army Retiring Board incapacitated for active service, on account
 of disability which is not the result of any incident of service, is
 by direction of the President, wholly retired from the service this
 date, under the provisions of Sections 1252 and 1275, Revised Stat-
 utes, and his name will be henceforward omitted from the Army
 Register. Par. 2, S. O. 54, A. G. O., Washington, March 10, 1891.
 Capt. Henry I. Raymond, Asst. Surgeon, is relieved from duty at
 Newport Bks., Ky., and assigned to duty at Ft. Thomas, Ky., re-
 porting in person to the commanding officer, Ft. Thomas, and by
 letter to the commanding General Div. of the Atlantic. By di-
 rection of the Acting Secretary of War. Par. 18, S. O. 54, A. G. O.,
 Washington, March 10, 1891.

*Official List of Changes in the Medical Corps of the U. S. Navy, for
 the Two Weeks Ending March 17, 1891.*

Surgeon M. L. Ruth, granted one month's sick leave.

Asst. surgeon S. G. Evans, detached from Naval Academy, and to
 the "Monongahela."

Surgeon A. F. Price, ordered to the U. S. S. "Monongahela."

Asst. surgeon H. N. T. Harris, ordered for examination prelimi-
 nary to promotion.

Asst. Surgeon George McC. Bicknell, ordered for examination pre-
 liminary to promotion.

P. A. Surgeon Ernest W. Auzel, ordered to the U. S. S. "Lancaster."

P. A. Surgeon Jas. H. North, Jr., ordered to the U. S. S. "Lancaster."

Surgeon James H. Games, ordered before the Retiring Board,
 March 12.

P. A. Surgeon G. W. Kite, from New York Hospital and to the
 "Lancaster."

Asst. Surgeon J. H. North, Jr., detached from the "Lancaster," and
 wait orders.

Asst. Surgeon G. T. Smith, from the "Independence" and to the
 "Lancaster."

Asst. Surgeon George A. Lung, from the "Mohican" and to Wash-
 ington, D. C., in charge of insane patients.

*Official List of Changes of Station and Duties of Medical Officers of
 the U. S. Marine Hospital Service, for the Three Weeks Ending
 February 8, 1891.*

P. A. Surgeon W. J. Pettus, relieved from special duty as Inspector
 of Immigrants at Port of Boston, Mass. Ordered to Marine Hos-
 pital, Boston, Mass., February 10, 1891.

Asst. surgeon T. B. Perry, granted leave of absence for thirty days,
 February 20, 1891.

Asst. Surgeon H. T. Goodwin, relieved from duty at Cincinnati, O.,
 ordered to Marine Hospital, New York City, February 8, 1891.

Asst. Surgeon E. Coffey, detailed for special duty as Inspector of
 Immigrants, Port of Boston, Mass., February 10, 1891.

Asst. Surgeon J. M. Eager, assigned to temporary duty at Cincin-
 nati, O., February 20, 1891.

APPOINTMENT.

Eager, John M. of Pennsylvania, commissioned as Asst. Surgeon
 by the President, February 16, 1891.

ORIGINAL ARTICLES.

THE INFLUENCE OF THE POSITION OF
THE PATIENT IN LABOR IN CAUS-
ING UTERINE INERTIA AND
PELVIC DISTURBANCES.

Read before the Gynecological Society of Boston, December 11, 1890.

BY AUGUSTUS P. CLARKE, A.M., M.D.,
OF CAMBRIDGE, MASS.

It has been generally taught that during the first stage of labor the patient may be allowed to assume that position which she considers the easiest for herself. Some accoucheurs encourage the patient not to take to the bed at the beginning of labor, but for the influence of the pressure of her own hands and the weight of the fetus in aiding flexion of the head and in promoting dilatation of the cervix, to maintain the sitting or upright posture. In the early stage, the dorsal position is often assumed; later, for convenience in making frequent inspection of the perineum, in assisting to carry out certain manipulative procedures, and in giving the necessary attention to uterine and rectal discharges, the left lateral posture is often advised. Some place the patient on the side to which the occipital presentation is inclined. Some reverse the position by placing the patient on the side toward which the sinciput or the vertex is descending. Women of the lower classes of some countries, while in labor, place themselves on their hands and knees. Other positions are sometimes assumed, such as half-sitting or partially reclining postures. Some women persist in standing or in getting on their knees. Formerly, the French women were delivered while in the dorsal position, with knees drawn up. In other countries, especially among the Aborigines, or among the half-civilized orders, many strange and singular positions have been assumed by women when in labor. Inquiry into the purpose for which any of the various positions which women have from time to time assumed while in labor, will show that the choice has been made more from the force of custom, from caprice, ignorance, and from a blind submission to authority—exercised by those who make unwarrantable pretensions to skill in midwifery, than from

knowledge deduced from facts gained by careful study and close observation.

The left lateral posture, with thighs drawn up and legs flexed upon the thighs, the shoulders projecting forward and the spine curved, has been thought to be more favorable for relaxation of the psoas and other muscles traversing the brim of the pelvis. This position has also been thought to be more favorable, as the axis of the entrance of the pelvis and that of the trunk would be on the same line, or be nearly parallel. Those who place their patients in such posture look upon the phenomena of parturition as dependent on mechanical forces, and not on the physiological function of the uterus and the powers of the system generally. The effectiveness of the uterine pains has been increased by change of posture, especially after the patient has maintained for a long time a constrained position. Under such circumstances, a mere temporary relief from a too irksome restraint has been followed by an increase in the general character of the pains which has more than counterbalanced any deficiency in the advantage of a better mechanical position. Women who are of a nervous temperament often find it exceedingly difficult, in the second, as also in the first, stage of labor, to undergo the fatigue of any one position for a considerable length of time. The vital forces of the system generally are often the first to suffer, and this fatigue quickly extends to the nervous force resident within the uterine and adjacent muscular tissue. The exhausting effects of a constrained position cannot be wholly overcome by the employment of anesthetics, for often the only manifestation of an expression of the baleful effects of too long constrained position is in the failure of the power of the uterine pains. The patient then begins to complain of weakness, she appears unable, or at least is unwilling, to move or to alter her position in bed. She may call for ether; if she is indulged by its employment the beneficial effects which follow are the result of its stimulating properties, and from change of position for its administration. If, unfortunately, the position is not materially altered, and the second stage of labor is not near its termination, the increased power in the pains derived by its administration will soon cease, and the patient will lapse into a state worse than the

one before its attempted administration. Fortunately, on the other hand, in such cases, in which ether is given with only temporary benefit, early in the second stage of labor, it is often deemed advisable to withhold it until the patient regains more or less consciousness. The outcries of the patient then for more ether, and the changes of position in bed she frequently makes, notwithstanding the severe restraint imposed upon her by the attendants, serve to increase the power of the pains and to bring to happy termination the second stage of labor.

Besides the occurrence of uterine inertia from long-continued position of the patient in labor, other disturbances are liable to arise. The effects of the blood pressure, and the gravitating of fluids toward the left uterine appendages and the peri-uterine structures, when the patient occupies for a long time the left lateral posture, should not be overlooked. Such untoward effects are particularly apt to follow in cases of those who suffer from cardiac affections, from disease of the lungs, bronchial tubes, kidneys, from general or partial cedema, and from deficient circulation. As already stated, parturition is not a mechanical but a physiological function, dependent upon a force having its origin in the nerves distributed to the uterine tissue and to the system generally. Whatever, therefore, tends to exhaust the general system, interferes with the normal action of the parts, and disturbs the proper function of the uterine tissue. When such disturbances are imparted to structures outside of the uterine walls, they are not easily overcome, but leave their impress more or less indefinitely on the parts involved. The great impressibility—as well as sensibility—which women acquire even in the early stage of pregnancy, is well shown by the development of that peculiar appearance denominated mother's marks which sometimes occur on the cutaneous surface of the child. It is not only in the early stages of pregnancy, but in every stage of that condition, and even for some time after delivery, that this highly sensitive condition obtains, leaving its impressibility more or less permanently not only on the fetus, but also on her own tissues adjacent to the uterine structures.

Among the puerperal lesions which may result from the lateral posture too long retained are affections of the bladder. The prolonged pressure of some portion of the fetus on the sensitive bladder arrests to a considerable degree the normal action of that viscus. It thus weakens its integrity—causes inflammation of the mucous surface. The inflammation in the bladder is prone to extend backward into the ureter. The ureter itself, on one or both sides, taking on inflammatory processes becomes distended with unhealthy urine. This may lead to rupture into the pelvic tissue, and thus give rise to sloughing or to the formation of abscess. I have notes of

the autopsy in the case of Mrs. E., who died during the third week after delivery. The death occurred after second confinement. The bladder throughout its entire surface was tumefied, red, and covered with dark, purulent fluid. The pelvis contained a quantity of semi-purulent exudation having the odor of urine. The left ureter was abnormally distended, it was inflamed and was found to have undergone rupture at a point three and one-quarter inches from the base of the bladder. The ureter on the right side, though somewhat inflamed from the contact with morbid urine, was not greatly distended. The history of the case showed that the patient was in labor some thirty-six hours, and that during the last twenty-three hours she had occupied for the most part the left lateral posture. The pelvis was well formed and of normal dimensions. The child was not large. It was born alive and did well. The cause of the delay in the delivery appeared to be owing to inertia into which the uterus had partially lapsed quite early in the second stage of labor. The patient had suffered from chronic cystitis and from marked anteversion of the uterus. Recto-vaginal and vesico-vaginal fistulae are lesions which now and then occur and which are largely the result of childbirth. Emmet mentions two hundred and two cases that were admitted to the Women's Hospital. One hundred and seventy-one of the cases were caused by child-birth. He says the average duration of the labor completed from rupture of the membranes was 58.69 hours. On another table he says 46.19 per cent. of the cases were delivered by forceps, and that the average duration of labor was 68.55 hours. Emmet does not coincide in the popular belief that instrumental delivery is the cause of fistulae. He rather attributes their occurrence to retardation in the progress of labor, induced by negligence to empty the bladder. Though he recognizes over-distension of the bladder as a factor in the production of fistulae, he does not appear to be wholly certain as to that condition of the patient being the final cause, for he says it is not improbable, since the averaged time is so long before the separation of the sloughs that the additional force in many cases necessary to effect the delivery may be the exciting cause of the inflammation. In six cases of vesico-vaginal fistulae whose histories I obtained, the additional factor could not be attributed to force necessary to effect delivery. It was clearly due to the position of the patient too long retained. In three of the cases the position was the left lateral, in two the dorsal; in one was the right lateral which the patient persisted in retaining for some forty-four hours.

Among the other inflammatory conditions which follow confinement are those of the uterine appendages. Sometimes we have salpingitis on one or both sides, but often more severe on one side. Sometimes the morbid process comes from

the escape of blood through the flimbriated extremity of the tube into the pelvic cavity. Some times we have following confinement an hæmatic tumor or cyst, and occasionally, if not often, hæmatosalpinx. All these lesions or morbid processes, whatever be their predisposing causes, are influenced more or less by posture of the patient.

Hæmorrhage from the lungs and from other organs, and from the vascular tissues, is greatly influenced by position. In the treatment and in the prevention of such symptoms position of the patient and of the parts must always be a factor for consideration. In the management of hæmorrhage and accidents peculiar to the puerperal state position of the patient becomes of still more consequence. This is rendered so not only on account of the extreme sensitiveness of the organs and the system generally but also on account of the development of that nervous function and the exhausting exercise of it necessary for production and accomplishment of parturition. Another condition sometimes following labor is subinvolution of the uterus. The cause of this condition has often been ascribed to laceration of the cervix. Cases of subinvolution now and then occur in which no appreciable laceration can be found to have taken place. In such cases in the absence of a history of an injury having been received it is usual to consider the cause to be want of tone in the pelvic venous circulation.

I have the history of two cases of subinvolution of the uterus, in which there was no laceration of the cervix nor of the perineum. Nor was there any reason to suspect that there existed in either case a perverted condition of the system generally. Neither patient had sustained injury immediately preceding or during parturition. In one case uterine dyskinesia was also a troublesome symptom. In the other case, though the subinvolution was not so pronounced, there was for a long time inability to walk (uterine lameness). There was an increase of the tendon reflex, and there were areas of much sensitiveness in the vicinity of the dorsal and lumbar vertebrae. The first patient was in labor forty-nine hours, but was delivered without instruments. She occupied for the most part the left lateral posture. The second patient was in labor fifty-three hours. She was delivered also without instrumental interference. She occupied almost continuously during labor the dorsal posture.

In conclusion I would say that I have chosen this subject for consideration not because I am now prepared to offer any special rules for guidance as to the position of the patient in labor, but from a conviction, deepening more and more by experience, that posture in some, if not in a large class of cases, is an important factor in the production of derangement of uterine force and also in that of pelvic disturbance. Such perversion in

the function of the uterine tissues and adjacent structures is liable to be looked upon as being the result of some possible defect in the parturient treatment in which all due and proper care may have been exercised, and not as the result of some other element in the management of the case for the reason of which it has not occurred to the medical attendant to make inquiries.

(For discussion see Society Proceedings.)

MIGRAINE AND FUNCTIONAL HEAD-ACHES FROM EYE STRAIN.

BY PETER A. CALLAN, M.D.

PHYSICIAN NEW YORK EYE AND EAR INFIRMARY.

Writers on nervous diseases, as a rule, devote considerable attention to migraine, its etiology and clinical phases. It is generally conceded that it is due to some special sources of irritation, whether in the stomach, uterus, eye or elsewhere in the system. The eye is often honored as a causative factor with the appropriate heading of "Ophthalmic Migraine." Physicians and scientists have recorded minutely and accurately, attacks occurring in their own persons. Among these, Wollaston stands preëminent as the first who drew general attention to one phase of this functional disturbance, viz.: temporary hemianopsia. A dissertation on the "Semi-Decussation of the Optic Nerves" was published by him in the "Philosophical Transactions" a few years prior to his death, which took place in 1806, from organic disease of the brain. In this paper he stoutly affirmed his belief in the semi-decussation of the nerves at the optic chiasm. He arrived at this conclusion by a study of his seizures of temporary homonymous hemianopsia. His experience led him to regard temporary hemianopsia as common in migraine seizures. Sir John Herschel, Sir Charles Wheatstone and Dr. Herbert Airy have recorded their special phases of the disease.

Parry, to whom credit is due for first having drawn attention to that complex disarrangement of several organs, which we now designate as Basedow's or Graves' disease. He described the eye symptoms occurring in his own person during migraine attacks as incomplete scotomata, lasting from twenty to thirty minutes. We find various names used to designate these attacks: migraine, megrim, sick or bilious headaches, hemicrania.

The influence of heredity is marked, and we find a neurotic element in many of the cases. Women are supposed to suffer much more frequently than men. Eulenburg states that the proportion is five to one. Three to two would be more in keeping with my record of cases. We find that migraine is likely to last from the fifteenth to the fiftieth year—the active period of life; that young children and quite old may suffer with it. In the majority of these attacks the pain is apt to begin

on one side of the forehead or temple, more often the left, involving the ophthalmic division of the fifth nerve with its branches, and at times the occipital and its branches, but in the severe seizures the pain is not confined to one side but includes both. In some the first manifestation is dizziness; in others the eye symptoms precede the head and stomach. After a variable interval of pain, the eyes become affected—perhaps a temporary blindness, half blindness or blur of objects, scotomata, light phenomena, which assumes in some cases fantastic shapes, great intolerance of light and noise; eyes become bloodshot and painful, especially when the eyes move in their sockets. This lasts from fifteen minutes to half an hour; then the stomach manifestations are in order; this varies from mere nausea to the most violent retchings and vomiting. This is usually the turning point of the attack, and if the patient can only get asleep, he awakens free from pain, but weak. The duration of an attack may be from a few hours to two days.

The subdivision of migraine into anæmic and congestive types as a classification has something to recommend it, but in practice the exceptions outnumber those that follow the rule. Even in the same individual the attacks vary in duration and severity, sometimes being so slight that all ordinary routine work is done without much disturbance, while again the head, eye and stomach symptoms are so severe that life is not worth living. The patient lies in bed utterly prostrated, pale, drawn countenance, racked with pain and vomiting, unable to bear the slightest noise, while light is simply intolerable—a picture of misery. Liveing's appellation, "nerve storm," becomes very appropriate.

These nerve storms vary in frequency from only a few in the course of a year to one or two in a week. This difference we attribute to the health of the patient, and in the main we are correct. At the same time, if we question closely such a patient, we find that headaches are of very frequent occurrence, oftentimes daily; they have become so common that they accept them philosophically. The pains extend across the brows, temples, back of head and even descending down the cervical vertebrae. Close work is certain to produce a headache; so is shopping, watching a play at the theatre, or looking out of a car window while traveling, and if the headache is not an immediate sequence it is likely to come on the next morning. I have known patients who could not look at a floor of square marble tiles or patterns of wall paper without a headache, even at times amounting to migraine.

Many of these sufferers are nervous and irritable, especially if the health is below par. Trifles upset them, and not a few pass into an neurasthenic condition. Stevens, in his book on "Functional Nervous Diseases," gives it as his experi-

ence that the eyes are the most prolific source of nervous disturbances, and more frequently than any other conditions contribute a neuropathic tendency.

As to the pathology—the views are as numerous as the observers.

Du Bois Reymond, in 1860, arguing from his own personal manifestations of migraine, held that there is a tetanic condition of the vessels of the affected side, with involvement of the cervical sympathetic. Mollendorf maintains that there is a dilatation of the vessels due to paralysis. Liveing, that there is a nerve storm passing through the centres at certain intervals constituting an attack of migraine. Latham, that owing to a spasm of the vaso-motor nerves there is primarily a condition of anæmia of the parts of the brain affected.

In all probability each of the views expressed describes one stage and only so much: that the hemianopsia scotomata and other ocular phenomena result from anæmia of the controlling cerebral centres, and are due to the contraction of the capillaries, brought about by irritation of the sympathetic vaso-motor nerves. This stage is but temporary, not exceeding an hour at most, and is followed by a stasis or congestion, causing the pain within the brain, followed by stomach and other disturbances. There are no two eyes exactly alike—we unconsciously use the better eye more than its fellow, hence the one-sided pain in mild attacks.

Binocular vision is a very complex performance, demanding for its accomplishment the harmonious coöperation of several cerebral centers—cranial nerves and the sympathetic system. The 2d, 3d, 4th, and 6th, and perhaps in a measure the 5th cranial nerves, as well as the sympathetic, are called into play. One or more parts of this system may be defective, thereby throwing extra strain on the others. The refraction of the eyes is usually at fault, with secondary involvement of the muscles—ciliary and external ocular muscles. A common illustration of this is seen in convergent squint, owing to a deficient refraction of the eyes—it becomes easier to sacrifice binocular vision and work with one eye. The result is that the external rectus of squinting eye becomes weak, while the contracted internus is over developed.

To the memory of Donders mankind owes an undying debt for his classic work. He placed the refractive errors of the human eye on a scientific basis. To give some idea of the misconceptions that were extant with regard to the refractive errors I will quote Mackenzie, a great authority in his day and that not fifty years ago, while writing about presbyopia, or farsight. He states when it came on suddenly much under the age of forty it was due to *some disease within or behind the eyes*. It was even observed in chil-

dren; in all such cases evacuating remedies were found useful. Leeches to the temples; blisters behind the ears and the use of purgatives. These, he naively remarks, generally cured. He quotes the case of a boy under Mr. Ware's care, whom the master at school frequently whipped on account of defective sight. Mr. Ware supplemented the school master's counter-irritation by evacuating remedies, and effected a cure. I have no hesitation in saying that refraction errors of high degree have great influence on the formation of the character. The young myope seeks companionship in his books—grows introspective—lives in an ideal or unreal world of his own creation; becomes bashful, diffident, and takes no part in the sports of his companions, so that his physique suffers. The hyperope with high degree of error learns but slowly on account of the great strain to see—books are to him distasteful—may be classed as a dullard by his parents and teachers—often censured unjustly, when really he has entered the race heavily handicapped.

Donders, in his classic work, states distinctly that the emmetropic, or normal eye, is one with a small amount of error, which must not exceed $\frac{1}{16}$ of hyperopia; while under astigmatism he writes, "so long as astigmatism does not essentially diminish the acuteness of vision, we call it normal, and if it amounts to $\frac{1}{16}$ or more it is abnormal."

Donders published his book over twenty-seven years ago and his observations were made in Holland. With regard to our country, at the present time, the errors which he accepted and called normal are too great to pass uncorrected, especially if the patient suffers from headache or other nervous disturbance. The hurry and excitement incidental to life, in a large city, combined with our stimulating climate, tend to exhaust the system much sooner than abroad.

Every organ has its limitations of work and endurance, and the human eye is no exception to this rule. Further, a normal eye is the exception, and when we impose on exact of our eyes an amount of work that calls for very great strain to accomplish, pain and nervous disturbances are most likely to develop. I do not advocate that all refractive errors of the human eye should be corrected, but if we have reason to suppose that such errors are prejudicial to the comfort and health of a patient, it becomes our duty to have that strain removed by suitable glasses. When vision is poor and the daily avocation demands good sight, correction is in order as a matter of course. With the aid furnished satisfactory work can be accomplished, and the eyes used within the ordinary physical limitations, which we must all learn for ourselves. As a rule it is not such cases that perplex a physician, for if there is any oblivious defect of sight, with pain and blur following the use of eyes, the patient may know of

the defect and mention the fact, but this does not necessarily follow.

The difficulty is with the masked cases of refractive error, when the vision is excellent and a fair amount of work done without much apparent discomfort. The majority of patients claim that their vision is excellent, when, in fact, oftentimes it is quite indifferent. Questions as to the eye strains are stoutly denied, not through any wrong motive, but they have such abiding faith in the excellence of their eyes; and further, few persons study themselves carefully. Any headaches or migraine attacks are promptly attributed to some cause, dyspepsia, liver, or neuralgia, and then they have always suffered, at least for many years, that one or the other of the parents, suffered in a similar way, and how can they expect to escape.

I well remember the case of a lady ten years ago who had long and frequently suffered from migraine, who was cured by wearing glasses. When I first suggested to her that her eyes were at fault she remarked that it was impossible, for her vision was excellent and none of the many physicians whom she had consulted, both at home and abroad, never even mentioned such a thing.

In very many of these cases distant vision is good and if they could be ranchmen, sailors, or lead a pastoral life, there would be but little trouble worth mentioning.

In examining patients who suffer from functional headache and migraine we should resort always, when it is possible, to mydriatics, so as to put the ciliary muscle at complete rest. There are quite a number to select from—sulph. atropiæ is most generally used, but where time is of importance we can get satisfactory results from a combination of homatropine and cocaine—two per cent. to four per cent. solution; the effects pass off in about twenty-four hours. No one is justified in excluding the eyes, as a cause, until a thorough examination is made, as to refractive errors, under complete ciliary paralysis. I have frequently found that correcting 0.25 D. of astigmatism has given complete relief.

In testing eyes the accepted standard of $\frac{1}{30}$ vision is only a guide, for with young patients $\frac{1}{40}$ is not very exceptional. So that a glass in such a case, that gives a vision of only $\frac{1}{40}$, is not the correction and we should look further. If we find that a convex glass appears to correct—try and see if a combination of a weaker convex with a weaker cylinder does not do equally as well, if not better. To any one who has much experience in this line, it is often surprising to note the various combinations which appear to give equally good vision, viz.: $\frac{1}{30}$ in a given case, and often considerable care must be exercised in deciding which gives the best results on the astigmatic chart and test type card.

Always fully correct the astigmatic error, but

in respect to the ametropia which may exist, too many factors have to be considered to discuss the subject in this paper. Test ocular muscles before and during the accommodative paralysis. It will be found that the results vary very much at different examinations. I am of the opinion that the eye strain makes faulty ocular muscles and generally, the ametropia satisfactorily corrected, the muscles will not be a disturbing factor. Hypermetropic astigmatism furnishes the greatest number of cases for the simple reason that myopia is rare, comparatively speaking, when we consider the whole population.

Correct for distance and near work; insist on the continuous wearing of the glasses, but here we strike a snag, for many, especially women, will not wear glasses out of doors. They would rather take antipyrin, or some similar drug, when they have migraine.

In conclusion—from an extended experience of years, with hundreds of cases, I am forced by experience to regard eye strain as the cause in over seventy-five per cent. of all the cases of functional headache and migraine.

THE INFLUENCE OF GERMAN UNIVERSITIES UPON OUR PROFESSION.

Read before the American Academy of Medicine, at its Fourteenth Annual Meeting at Philadelphia, December 7, 1890.

BY HENRY E. DWIGHT, A.M., M.D., D.D.,
OF PHILADELPHIA, PA.

From the minutes of the Council, I extract the following authority for the selection of my subject, and its presentation at this meeting of the Academy:

In accordance with the leading objects of our organization, the education of the physician, both preliminary and technical, the relations of the profession in this country to that of other countries, and the elevation of the literary, scientific and social standing of the Profession, are especially appropriate subjects.

In view of the fact that the constitution was altered at the last annual meeting so as "to admit, in addition to those possessing the degrees of A.B. and A.M., those who can present evidences of preparatory liberal education equivalent to the same"—the subject proposed in the following paper is of vital importance at this meeting of the Academy.

INFLUENCE OF GERMAN UNIVERSITIES UPON THE MEDICAL PROFESSION.

1. *What is a University?*

It is one thing in America, another in England, and something else in Germany. Hence the importance of a clear definition. The University of London has no teachers, no scholars, no buildings, except a room in Burlington House, no libraries, no laboratories, and yet it has a brilliant staff of Professors in the Scientific and Medical Depart-

ment. It is simply the Napoleonic University of France without the principle of teaching. Why not, therefore, have a University without teachers, in this age of printing, of many books on every subject? Because, the mind, the voice, the eye of the living instructor is as necessary to-day as in the days of the Athenian Agora or Academia, with Plato, Aristotle, Socrates and their pupils. In Germany by these means Hegel in philosophy, Dörner in theology, Hoffman in chemistry and von Virchow in physiology, have been equally successful.

Hence a University is a body of instructors, teaching the highest knowledge, of the most worth to men, dealing with their dearest interests, appealing to their finest powers and noblest feelings. To aid them in this blessed work let the University prescribe certain courses and what rewards shall follow a complete and thorough training; and not for these alone, but let them arrange for those who thirst for knowledge, and earnestly desire the best sources, who should be welcomed to lectures suited to their needs, just as hungry souls pass through church doors always open to satisfy their wants. Therefore Universities must teach, must vivify knowledge, by appeals to the discursive reason and the creative imagination. But they must do more. Among the services they render when rightly conducted, is the prosecution of scientific research into facts imperfectly examined. True teachers are always progressive and not content with imparting the conclusions of others. They are investigators for testing the observations of their predecessors, while reaching their own conclusions. In the natural sciences, they will observe phenomena, collect and classify observations, draw inferences and force nature to give up her secrets by experiments. Among the greatest teachers in science a large number have been and are now, discoverers.

In such an institution, famed for its teachers and its original researches, a young student in medicine escapes exclusiveness, because the methods of one science are corrected by those of another. In such an atmosphere, theologians and mathematicians are not intolerant of the votaries of natural science. The student sees a host of men, eminent in genius and industry, who enlarge his horizon by bearing her torch into abstruse paths of knowledge, to masterpieces of thought and feeling which bear fruit in his own mind through life. Hence the Catholicity of his views, the elevation of his feelings and the success of his pursuits.

2. *But what claims have the German Universities on our peculiar attention to-day?*

Montesquieu, in his "Spirit of the Laws," declared that the English Constitution is found in the forests of Germany, which is abundantly confirmed by Tacitus, and in later days by Palgrave, Kemble and Sir Henry Maine. English customs

and laws migrated with the Pilgrims to America. The Germanic System of common fields was revived as Commons or Town Lands in New England. The Saxon Hege, Warden of the Hedge, was the pound keeper of the United States. In the Mayflower's cabin was representative government, and in the Pilgrim's soul there was reverence for law, to be maintained in a legalized, organized town, with a church for God's worship and a seminary of learning for man's welfare, on which rested the institutions of a new world. Hence Harvard and Yale are the legitimate offspring of Teutonic ideas and German ideals—the "Alma Mater" of a numerous family.

German Universities are controlled by the ideas that *national unity* depends on *national culture*, that the *powers* that be are ordained of God, and that *rulers are to be obeyed*, if they consecrate their *power to the welfare of the whole people*. The instruction is by means of lectures, and the discussions are conducted by the professors. With the highest instruction in theory are combined laboratories, clinics, and the best apparatus for observation and experiment, to secure practical instruction. Diligence and scholarship are rewarded by degrees which the student must have before he can graduate or enter a profession. Our colleges are stepping-stones, like their gymnasia, to a university. We have no institution which the Germans will recognize as a university, and they have none which an intelligent American would recognize as a college. Their high schools, with a six years' course, furnish a general education, not a liberal one, and are designed to prepare students for business life. The school for liberal education is the *Gymnasium*, with a nine years' course, which pupils begin at nine years of age. Linguistic and historical studies are the peculiar principle of the gymnasium, and as the Minister of Education, von Gosler, officially declared in 1882, "are designed to prepare for independent study at the University."

The *Real Schools*, the rivals of the gymnasia, have received their inspiration from the people, and were promoted by progress in natural science, industrial pursuits, and in realism, instead of idealism. They emphasized modern languages, history, mathematics and natural science. The *real* was to be secured by the *Real Schools*. But German scholars are not prepared to sever scholarship from the ancient classics, to take in their place the modern languages, or translations of the ancient—and the German Government prefers the gymnasium, for every position in its gift is accessible to its graduates. German physicians are not ready for such a change, for out of 163 Medical Societies only three gave their unqualified consent for the admission of students in the Real School to the University Medical Department. There are serious complaints by the German Government respecting the efficiency of their

medical students, and fear lest the change in the standard of admission to the University Medical Department might lower the standard of scholarship. They favor an increase of the study of medicine from four to five years, to secure better preparation for the faculty.

The testimony of that eminent chemist, Prof. A. W. Hoffmann, rector of the University of Berlin, is very important to all liberally educated physicians. He is certainly one of the ablest instructors in that great University, and means what he says, viz.: "That all efforts to find a substitute for the study of the ancient classics, whether in the modern languages, mathematics, or natural sciences, have thus far proved a failure. How often have I heard young men prepared in Real Schools deeply regret that they had not enjoyed the training of a gymnasium. The ideality of academical study, the unselfish devotion to science as science, the free exercise of thought, the condition and result of this devotion recede in proportion as the classic basis, as training for the university, is withdrawn. I have had much occasion to speak of this matter with friends devoted to physics and mathematics, and with scarcely an exception I found they had the same conviction." These are strong words, and merit careful consideration. Similar testimony, as to the value of a classical education, has been given by Liebig, the father of agricultural chemistry, Wolff, Henneberg, Knap, Nolbe, Stohmann, Kühn and others, all of whom are well-known chemists and discoverers in Germany.

3. *Does the History of Medicine confirm these Claims?*

Are we members of a learned profession? Should we rank with lawyers and theologians on University Catalogues? Have we a scientific profession?

These are important questions in America as well as in Germany. Let us see. Homer mentions two physicians, Machaon and Podalirius, skilful in stanching wounds and relieving pain. The story of Esculapius proves that is far back as legendary history, men made disease and the healing art a special study, and lived by the practice of their craft; but their observations and theories were worth little, because their philosophy was so crude. The labors of Hippocrates are constantly marred by his identification of effect with cause, restrictions placed on the dissections and undeveloped collateral science, still his work is a monument of unwearied industry and wonderful fidelity to nature. The signs of facts, for the facts themselves, or effects taken for causes, ruined every system of nosology from Hippocrates to Cullen.

There was no sound anatomy or physiology to solve the problems of the diseased system, and not until the *anatomic method* of the Alexandrine School pointed to dissection and un-

locked the human frame, that true light revealed the phenomena of disease. Herophilus, their most celebrated teacher, made six hundred dissections, and acquired such distinction that the proverb remains to this day, "To contradict Herophilus is to contradict the Gospel." But the famous fire at Alexandria destroyed his researches with the Library, but not the principles which they discovered, for Philinus, his disciple, left the most important system of early medicine. Philinus urged a return to observation and clinical studies, and was surrounded by a host of observers, among whom was the celebrated Heraclides of Tarentum, who first introduced opium into practice.

So far, scientific medicine is confined to a University, Alexandria, with its literary treasures and learned men. Let us pass from the East to the West, from Egypt to Italy. Pliny assures us that the Roman people had been without a physician for six hundred years. In some things the world is not wiser now than at that period. Then people resorted to certain temples, even in the severest epidemics, as now to the shrine of St. Vitus, where the "Faith Cure" had its most numerous disciples as well as victims. St. Ossi-fya cared for the growth of bones at Rome, just as St. Ursula now cares for them when dead in the Church of the 11,000 Virgins at Cologne.

In Rome, and at this epoch, appeared the elder Pliny, who collected in his "*Historia Mundi*," all the systems from Hippocrates to his own, and has left in his history many original views and reflections, as evidence of the profound mind of a great naturalist. From Pliny to Galen, the inquiries multiplied exceedingly, because Galen revived the principles of the great physician of Coos, and held undisputed sway in medical matters till the sixteenth century. Devoted to anatomy and physiology, especially the former, his authority became as infallible in medicine as that of Aristotle in philosophy. With Galen, early medicine lost its greatness, and with the downfall of the Roman Empire it retrograded likewise, but during the history of that Empire, so far as progress was made in the principles and practice of our art, it was on a *scientific* basis. Esculapius was enthroned at Rome, and not at Canossa.

The age of Dante was the period of the renaissance, when science was divorced from superstition and charlatanism. The first modern dissection of the human subject was made by Mondini di Luzzi, towards the close of the sixteenth century, when the tone of the European mind influenced art as well as medicine, but the public authorities censured Mondini, and dissections ceased. In the sixteenth century, Vesalius resumed them, and laid the foundation of modern anatomy. The purity of his intentions and his noble views removed popular prejudice, which enabled Ambrose Paré, first to turn to practical use the labors of his

predecessors, and as surgeon to several European sovereigns, by systematizing the researches of his predecessors, to lay foundations for the structure reared by John Hunter, Dupuytren, Abernethy and Sir Astley Cooper. During the eighteenth and nineteenth centuries such stars of the first magnitude as Morgagni and Scarpa in Italy; Haller, Boerhaave, Heister and Soemmering in Germany; Dupuytren and the illustrious Bichat in France; Cullen and the Hunters in England—all eminent physicians and surgeons, continue the work of scientific research in medicine, and science based on facts and not on theoretic principles, in a field of enquiry commensurate with the three physical kingdoms of nature.

Surely, the Germans have not erred in their estimate of a classical and scientific training for a physician up to the nineteenth century, if the history of our profession means anything in the development of the race.

What shall I say of *our* century, now drawing to a close? How the labors of our predecessors pale before the wonders of the nineteenth century! Physical examinations, chemical tests, microscopical histology, anesthetics in surgery, have certainly elevated medicine to a science, and its practitioners to the front rank of her votaries, entitled to the respect and gratitude of all enlightened men. Every tissue of the body is under the microscope, all living organisms are the products of elementary cells, so that every difference of structure implies a difference of function. Thus we mount from the simple cells to the marvelous structure, man, the paragon of animals, the beauty of the world. Under the careful studies of the German, Kolliker, the liver is revealed as a complex and beautiful structure, symmetrical in design, with an arrangement of lobules, cells, nerves and blood-vessels, worthy of the warmest admiration, not simply to make bile, but to repair the waste of nerve tissue. No less the eye, when under the microscope, bears the happiest results. The discovery of the retinal expansion of the optic nerve or Jacob's membrane, has wonderfully elucidated the phenomena of vision. Those nerve fibres are specially fitted to the undulations of light. What a change in our theories of color vision! Anesthetics have robbed surgery of all its cruelty and half its danger, extended its sphere of action, increased the proportion of recoveries after severe wounds and mutilations, and insured the safety of obstetrics. Within fifty years the operation for stone will become obsolete. Small pox is no longer a possible danger to life. Typhoid fever is rarely fatal and typhus is almost unknown, except in the wake of armies or famine. Madness is now a curable disease, and the drugs employed are less loathsome than the disease. Fluid extracts and active principles take the place of nauseating powders and tinctures. The causes of disease

are more thoroughly studied and better understood. From a cold in the head to pulmonary phthisis, from lupus to cancer, Bacillus is the password, no matter what may be the "Grippe." Query. Is the Bacillus the cause or a consequence of the disease? Let that star of the first magnitude now in the zenith at Berlin so guide our wise men, now about to visit him from the East, that we may all have a quick deliverance from the scourge of mankind.

Mr. President and Fellows of the Academy, I thank you for your patient attention. May I ask for your careful consideration?

AMERICAN MEDICAL ASSOCIATION.

Plan of Organization for a National Medical Association.

WHEREAS, The Medical Convention, held in the city of New York, in May, 1846, have declared it expedient "for the medical profession of the United States to institute a National Medical Association;" and,

Inasmuch as an institution so conducted as to give frequent, united and emphatic expression to the views and aims of the medical profession in this country, must at all times have a beneficial influence, and supply more efficient means than have hitherto been available here for cultivating and advancing medical knowledge; for elevating the standard of medical education; for promoting the usefulness, honor, and interests of the medical profession; for enlightening and directing public opinion in regard to the duties, responsibilities, and requirements of medical men; for exciting and encouraging emulation and concert of action in the profession, and for facilitating and fostering friendly intercourse between those who are engaged in it; therefore, be it

Resolved, In behalf of the medical profession of the United States, that the members of the Medical Convention, held in Philadelphia, in May, 1847, and all others who, in pursuit of the objects above mentioned, are to unite with or succeed them, constitute a National Medical Association; and that for the organization and management of the same, they adopt the following *Regulations*:—¹

I.—TITLE OF THE ASSOCIATION.

This institution shall be known and distinguished by the name and title of "The American Medical Association."

II.—MEMBERS.

The members of this institution shall collectively represent and have cognizance of the common interests of the medical profession in every part of the United States; and shall hold their appointment to membership either as delegates from local institutions, as members by invitation, as permanent members, or members by application.

The *Delegates* shall receive their appointment from permanently organized State medical societies, and such county and district medical societies as are recognized by representation in their respective State societies, and from the medical department of the Army and Navy of the United States, and the Marine Hospital Service of the United States.

Each delegate shall hold his appointment for one year, and until another is appointed to succeed him, and shall participate in all the business and affairs of the Association.

¹ Revised to date

EDUCATIONAL POSITION OF BERLIN.—There are 5,527 students in attendance upon the different faculties of the University of Berlin, which places it at the head of all the German universities. Throughout Germany there are nearly 30,000 students in attendance at twenty universities.

Each State, county and district medical society, entitled to representation, shall have the privilege of sending to the Association one delegate for every ten of its regular resident members, and one for every additional fraction of more than half that number; *Provided*, however, that the number of delegates from any particular State, Territory, county, city, or town shall not exceed the ratio of one in ten of the resident physicians who may have signed the Code of Ethics of this Association. The Medical Staffs of the Army and Navy shall be entitled to four delegates each. The Marine Hospital Service of the United States shall be entitled to one delegate.

No individual who shall be under sentence of expulsion or suspension from any State or local medical society of which he may have been a member, or whose name shall have been, for non-payment of dues, dropped from the rolls of the same, shall be received as a delegate to this Association, or be allowed any of the privileges of a member, until he shall have been relieved from the said sentence or disability by such State or local society, or shall have paid up all arrears of membership; nor shall any person not a member and supporter of a local medical society, where such a one exists, be eligible to membership in the American Medical Association.

No one expelled from this Association shall at any time thereafter be received as a delegate or member, unless by a three-fourths vote of the members present at the meeting to which he is sent, or at which he is proposed.

Members by Invitation shall consist of practitioners of reputable standing from sections of the United States not otherwise represented at the meeting. They shall receive their appointment by invitation of the meeting, after an introduction from, and being vouched for by, at least three of the members present, or three of the absent permanent members. They shall hold their connection with the Association until the close of the annual session at which they are received; and shall be entitled to participate in all its affairs, as in the case of delegates, except the right to vote.

The *Permanent Members* shall consist of all those who have served in the capacity of delegates, and of such other members as may receive the appointment by unanimous vote, and shall continue such so long as they remain in good standing in the body from which they were sent as delegates, and comply with the requirements of the By-laws of the Association. Permanent members shall at all times be entitled to attend the meetings, and participate in the affairs of the Association, so long as they shall continue to conform to its regulations, but without the right of voting; and, when not in attendance, they shall be authorized to grant letters of introduction to reputable practitioners of medicine resid-

ing in their vicinity, who may wish to participate in the business of the meeting, as provided for members by invitation.

Members by Application shall consist of such members of the State, County and District Medical Societies entitled to representation in this Association as shall make application for admission, in writing, to the Treasurer, and accompany said application with a certificate of good standing, signed by the President and Secretary of the Society of which they are members, and the amount of the annual fee, five dollars. They shall have their names upon the roll, and have all the rights and privileges accorded to permanent members, and shall retain their membership on the same terms.

Every member elect, prior to the permanent organization of the annual meeting, or before voting on any question after the meeting has been organized, must exhibit his credentials to the proper committee, and sign these regulations, inscribing his name and address in full, specifying in what capacity he attends, and, if a delegate, the title of the institution from which he has received his appointment.

III.—MEETINGS.

The regular meetings of the Association shall be held annually. The place of meeting shall be determined, with the time of meeting for each next successive year, by vote of the Association.

IV.—OFFICERS.

The officers of the Association shall be a President, four Vice-Presidents, one Permanent and one Assistant Secretary, a Treasurer, and Librarian. They shall be nominated by a special committee of one member from each State represented at the meeting, and shall be elected by vote on a general ticket.

Each officer except the Permanent Secretary, shall hold his appointment for one year, and until another is elected to succeed him. The Permanent Secretary shall hold his appointment until removed by death, resignation, or a vote of two-thirds of the members present at a regular annual meeting.

The President and Vice-Presidents shall assume the functions of their respective offices at the beginning of the annual meeting next succeeding their election; all other officers shall enter upon their duties immediately after their election.

The *President* shall preside at the meetings, preserve order and decorum in debate, give a casting vote when necessary, and perform all the other duties that custom and parliamentary usage may require.

The *Vice-Presidents*, when called upon, shall assist the President in the performance of his duties, and during the absence, or at the request

of the President, one of them shall officiate in his place.

The Permanent Secretary shall record the minutes and authenticate the proceedings; give due notice of the time and place of each next ensuing annual meeting; notify all members of committees of their appointment, and of the duties assigned to them; hold correspondence with other permanently organized medical societies, both domestic and foreign; and carefully preserve the archives and unpublished transactions of the Association.

The Assistant Secretary shall aid the Permanent Secretary in recording and authenticating the proceedings of the Association; serve as a member of the Committee of Arrangements, and perform all the duties of Permanent Secretary temporarily whenever that office shall be vacant, either by death, resignation, or removal.

The Treasurer shall have the immediate charge and management of the funds and property of the Association. He shall give to the Board of Trustees bonds for the safe keeping and proper use and disposal of his trust. And through the same Board he shall present his accounts, duly authenticated, at every regular meeting.

The Librarian shall receive and preserve all the property in books, pamphlets, journals, and manuscripts presented to or acquired by the Association, record their titles in a book prepared for the purpose and acknowledge the receipt of the same.

V.—STANDING COMMITTEES.

The Committee of Arrangements shall, if no sufficient reasons prevent, be mainly composed of seven members, of whom the Assistant Secretary shall be one, residing in the place at which the Association is to hold its next annual meeting; and shall be required to provide suitable accommodations for the meeting, to verify and report upon the credentials of membership, to receive and announce all essays and memoirs voluntarily communicated, either by members of the Association, or by others through them, and to determine the order in which such papers are to be read and considered.

The Board of Trustees shall consist of nine members, three of whom shall be elected annually, on the nomination of the Nominating Committee, and shall serve for three years. It shall be the duty of this Board to provide for and superintend the publication and distribution of all such proceedings, transactions, and memoirs of the Association as may be ordered to be published, in such manner as the Association may direct, and in doing this it shall have authority to appoint an editor and such assistants, and determine their salaries, and procure and control such materials as may be necessary for the accomplishment of the work assigned to it. To further facilitate its

work, it shall be the duty of the Secretaries of the Association, and of the several sections during each annual meeting, or as soon thereafter as practicable, to deliver to the Board, or such editor or agent as it shall appoint, all such records of proceedings, reports, addresses, papers and other documents as may have been ordered for publication either in the general sessions or in the sections. All moneys received by the Board of Trustees, or its agents, resulting from the discharge of the duties assigned them, must be paid to the Treasurer of the Association, and all orders on the Treasurer for disbursements of money in any way connected with the work of publication, must be endorsed by the President of the Board of Trustees. It shall be the further duty of the said Board of Trustees to hold the official bond of the Treasurer for the faithful execution of his office, to annually audit and authenticate his accounts, and present a statement of the same in its annual report to the Association, which report shall also specify the character and cost of all the publications for the Association during the year, the number of copies still on hand, and the amount of all other property belonging to the Association, under its control, with such suggestions as it may deem necessary.

VI.—FUNDS AND APPROPRIATIONS.

Funds shall be raised by the Association for meeting its current expenses and awards from year to year, but never with the view of creating a permanent income from investments. Funds may be obtained by an equal assessment of not more than ten dollars annually, on each of the delegates and permanent members; by voluntary contributions for specific objects; and by the sale and disposal of publications, or of works prepared for publication.

The funds may be appropriated for defraying the expenses of the annual meetings, including the necessary expenses of the Permanent Secretary in maintaining the necessary correspondence of the Association; for publication; for enabling the Standing Committees to fulfill their respective duties, conduct their correspondence, and procure the materials necessary for the completion of their stated annual reports; for the encouragement of scientific investigation by prizes and awards of merit; and for defraying the expenses incidental to specific investigations under the instruction of the Association, where such investigations have been accompanied with an order on the Treasurer to supply the funds necessary for carrying them into effect.

VII.—PROVISION FOR AMENDMENT.

No amendment or alteration shall be made in any of these articles, except at the annual meeting next subsequent to that at which such amendment or alteration may have been proposed; and

then only by the voice of three-fourths of all the delegates in attendance.

Provided, however, that when an amendment is properly under consideration, and an amendment is offered thereto, germane to the subject, it shall be in order, and if adopted, shall have the same standing and force as if proposed at the preceding meeting of the Association.

BY-LAWS.

I.—ORDER OF BUSINESS.

The order of business at the annual meetings of the American Medical Association shall at all times be subject to the vote of three-fourths of all the members in attendance; and, until permanently altered, except when for a time suspended, it shall be as follows, namely:

1st. The calling of the meeting to order by the President elected the preceding year, or, in his absence, by one of the Vice-Presidents.

2nd. The report of the Committee of Arrangements on the credentials of members, after the latter have registered their names and addresses, and the titles of the institutions which they represent.

3d. The reception of members by invitation.

4th. The election of permanent members.

5th. The reading of notes from absentees.

6th. The hearing of the annual address of the President.

7th. The reception of the reports of all special committees and voluntary communications, and their reference to the appropriate Sections.

8th. The appointment of the committee of one from each State represented, to nominate officers of the Association, and to fill the standing committees.

9th. The reading and consideration of the reports of the Standing Committees, of Publication, on Prize Essays, and of Chairmen of Sections.

10th. Resolutions introducing new business, and instructions to the permanent committees.

11th. The selection of the next place of meeting.

12th. The report of the Nominating Committee, and the election of officers of the Association.

13th. Reports from the several Sections.

14th. Reading of the minutes by the Secretary.

15th. Unfinished and miscellaneous business.

16th. Adjournment.

II.—SECTIONS.

The general meetings of the Association shall be restricted to the morning sessions; and the afternoon sessions, commencing at three o'clock, shall be devoted to the hearing of reports and papers and their consideration, in the following Sections:—

1. Practical Medicine and Physiology.

2. Obstetrics and Diseases of Women.

3. Surgery and Anatomy.

4. State Medicine.

5. Ophthalmology.

6. Diseases of Children.

7. Dental and Oral Surgery.

8. Medical Jurisprudence and Neurology.

9. Dermatology and Syphilis.

10. Laryngology and Otology.

11. Materia Medica and Pharmacy.

On the second day of each annual meeting each Section shall nominate its own officers to serve for the next ensuing year, their duties to commence with the close of the annual meeting at which they are nominated and to continue until their successors are appointed.

The Section on State Medicine shall be composed of one member from each State, one from the army and one from the navy of the United States, representing, as far as practicable, the State Boards of Health. The officers of this Section to be also designated by the Committee on Nominations.

The Chairman of each Section shall prepare an address on the recent advances in the branches belonging to his Section, including such suggestions in regard to improvements or methods of work as he may regard important, and present on the first day of its annual session the same to the Section over which he presides. The reading of such address not to occupy more than forty minutes.

It shall be the duty of every member of the Association who proposes to present a paper or report to any one of the Sections, to forward either the paper, or a *title* indicative of its contents, and its *length*, to the Chairman of the Committee of Arrangements at least one month before the annual meeting at which the paper or report is to be read. It shall also be the duty of the Chairman and Secretary of each Section to communicate the same information to the Chairman of the Committee of Arrangements concerning such papers and reports as may come into their possession or knowledge, for their respective Sections, the same length of time before the annual meeting. And the Committee of Arrangements shall determine the order of reading or presentation of all such papers, and announce the same in the form of a programme for the use of all members attending the annual meeting. Such programme shall also contain the rules specified in the By-laws and Ordinances concerning the consideration and disposal of all papers in the Sections.

No paper shall be read before either of the Sections, the reading of which occupies more than twenty minutes. Such papers shall be referred by the Section to sub-committees specially appointed for their examination. The sub-committees shall be allowed thirty days for such examination; at the end of which time they shall for-

ward the papers to the Board of Trustees, with such recommendation as they may deem proper. The author of such papers, however, may read abstracts before the Section within the allotted twenty minutes. No member shall address the Section more than once upon the same subject, nor speak longer than fifteen minutes without unanimous consent.

All papers presented directly to the Association, and other matters, may, at the discretion of the Association, be referred to the various Sections for their consideration and report.

III.—STANDING COMMITTEES.

The following are the Standing Committees of the Association, to be filled by the Committee on Nominations, and to report at the next annual meeting subsequent to their appointment, namely, Committee of Arrangements, Board of Trustees, and Committee on American Medical Necrology.

The Board of Trustees shall append to each volume of the *Transactions* hereafter published, a copy of the Constitution, By-laws and Code of Ethics of the Association. It shall print conspicuously, at the beginning of each volume of the *Transactions* the following disclaimer, namely, The American Medical Association, although formally accepting and publishing the reports of the various standing committees, holds itself wholly irresponsible for the opinions, theories or criticisms therein contained, except when otherwise decided by special resolution.

The Committee on *American Medical Necrology* shall consist of one member for each State and Territory represented in the Association, whose duty it shall be to procure memorials of the eminent and worthy dead among the distinguished physicians of their respective States and Territories, and transmit them to the chairman of this committee on or before the 1st of April of each and every year.

IV.—THE PUBLICATION OF PAPERS AND REPORTS.

No report or other paper shall be entitled to publication in the volume for the year in which it shall be presented to the Association, unless it be placed in the hands of the Board of Trustees on or before the first day of July. It must also be so prepared as to require no material alteration or addition at the hands of its author.

Authors of papers are required to return their proofs within two weeks after their reception; otherwise they will be passed over and omitted from the volume.

Every paper received by this Association and ordered to be published, and all plates or other means of illustration, shall be considered the exclusive property of the Association, and shall be published and sold for the exclusive benefit of the Association.

The Board of Trustees shall have full discretionary power to omit from the published *Trans-*

actions in part or in whole any paper that may be referred to it by the Association, or either of the Sections, unless specially instructed to the contrary by vote of the Association.

V.—ASSESSMENTS.

The sum of five dollars shall be assessed annually, upon each delegate to the sessions of the Association, as well as upon each of its permanent members, whether attending or not, for the purpose of raising a fund to defray necessary expenses. The payment of this sum shall be required of the delegates and members in attendance upon the sessions of the Association previously to their taking their seats and participating in the business of the sessions. Permanent members, not in attendance, shall transmit their dues to the Treasurer.

Any permanent member who shall fail to pay his annual dues for three successive years, unless absent from the country, shall be dropped from the roll of permanent members, after having been notified by the Secretary of the forfeiture of his membership.

VI.—DELEGATES FROM THE MEDICAL STAFFS OF THE ARMY, NAVY, AND MARINE-HOSPITAL SERVICE.

Delegates representing the medical staffs of the United States Army and Navy, shall be appointed by the Chief of the Army and Navy Medical Bureaus, and the U. S. Marine-Hospital Service. The number of delegates so appointed shall be four from the army medical officers, and an equal number from the navy medical officers, and one from the Marine-Hospital Service.

VII.—DELEGATES TO FOREIGN MEDICAL SOCIETIES.

The President shall be authorized annually to appoint delegates to represent this Association at the meetings of the British Medical Association, the American Medical Society at Paris, and such other scientific bodies in Europe or other foreign countries as may be affiliated with us.

VIII.—DUTIES OF MEMBERS.

No one shall be permitted to address the Association, except he shall have first given his name and residence, which shall be distinctly announced from the chair, and the member may be required to go forward and speak from the stand, but not more than ten minutes at one time.

No one appointed on a special committee, who fails to report at the meeting next succeeding the one at which he is appointed, shall be continued on such committee, or appointed on any other, unless a satisfactory excuse is offered.

IX.—CONDITION EXCLUDING REPRESENTATION.

No State or Local Medical Society, or other organized institution, shall be entitled to representation in this Association that has not adopted its Code of Ethics; or that has intentionally vio-

lated or disregarded any article or clause of the same.

X.—OF THE PREVIOUS QUESTION.

When the previous question is demanded, it shall take at least twenty members to second it; and when the main question is put under force of the previous question and negative, the question shall remain under consideration the same as if the previous question had not been enforced.

XI.—JUDICIAL COUNCIL.

A council, consisting of twenty-one members, shall be appointed by the Nominating Committee, whose duty it shall be to take cognizance of, and decide, all questions of an ethical or judicial character that may arise in connection with the Association. Of the twenty-one members of the council first appointed the seven first named on the list shall hold office one year, and the second seven named shall hold office for two years.

With these exceptions the term of office of members of the council shall be three years, seven being appointed by the Nominating Committee annually.

The said council shall organize by choosing a President and Secretary, and shall keep a permanent record of its proceedings. The decisions of said council on all matters referred to it by the Association shall be final, and shall be reported to the Association at the earliest practical moment.

All questions of a personal character, including complaints and protests, and all questions on credentials, shall be referred at once, after the report of the Committee of Arrangements or other presentation, to the *Judicial Council*, and without discussion.

XII.—NEW BUSINESS.

No new business, resolutions by members, etc., shall be introduced at the general session of the Association except on the first and fourth days of meetings.

XIII.—OFFICERS AND COMMITTEES.

In the election of officers and appointment of committees by this Association and its President, they shall be confined to members and delegates present at the meeting, except in the Committee of Arrangements.

XIV.—ADDRESSES.

The Association shall annually elect, on the nomination of the Nominating Committee, three members of the profession, eminent in some of its departments, to deliver addresses in the general session of the next ensuing annual meeting—one on some topic or topics relating to general medicine, another relating to general surgery, and the third relating to public medicine, including under that head, hygiene, sanitation, prophylaxis, education and medical legislation, each of such

addresses not to exceed one hour in its delivery.

The following resolution was adopted at the session of 1888:

That in future, each delegate or permanent member, shall, when he registers, also record the name of the Section, if any, that he will attend, and in which he will cast his vote for Section officers.

Also, that the Permanent Secretary may be enabled to erase from the roll the names of those who have forfeited their membership, the Secretaries *are, by special resolution*, requested to send to him annually, a corrected list of the membership of their respective Societies.

ORDINANCES.

Resolved, That the several Sections of this Association be requested, in the future, to refer no papers or reports to the Board of Trustees, except such as can be fairly classed under one of the three following heads, namely: 1. Such as may contain and establish *positively* new facts, modes of practice or principles of real value. 2. Such as may contain the results of well devised original experimental researches. 3. Such as present so complete a review of the facts on any particular subject as to enable the writer to deduce therefrom legitimate conclusions of importance.

Resolved, That the several Sections be requested, in the future, to refer all such papers as may be presented to them for examination by this Association, that contain matter of more or less value, and yet cannot be fairly ranked under either of the heads mentioned in the foregoing resolution, back to their authors with the recommendation that they be published in such regular medical periodicals as said authors may select, with the privilege of placing at the head of such papers, "Read to the Section of the American Medical Association on the day of 18 ." (Vide *Transactions*, Vol. xvi, p. 40.)

Resolved, That, instead of yearly reprinting the list of members of the American Medical Association, the Board of Trustees be instructed to prepare and print in the *Transactions* an alphabetical catalogue triennially, containing a complete list of the Permanent Members, with their names in full, designating their residences, the year of their admission, the offices they have held in the Association, and, in case of death or rejection, the date thereof. (Vide *Transactions*, Vol. xvii, p. 33.)

Resolved, That no report or other paper shall be presented to this Association unless it be so prepared that it can be put at once into the hands of the Permanent Secretary, to be transmitted to the Board of Trustees. (Vide *Transactions*, Vol. xvii, p. 27.)

Resolved, That the Permanent Secretary hereafter and from this date be authorized to draw a

warrant upon the Treasurer for the expenses incurred in his attendance upon each session of the Association, and that the Treasurer is hereby instructed to pay the same. (*Vote Transactions*, Vol. xviii, p. 42.)

Resolved, That the faculties of the several medical colleges of the United States be recommended to announce explicitly in their annual announcements, circulars and advertisements that they will not receive certificates of time of study from irregular practitioners, and that they will not confer the degree upon any one who may acknowledge his intention to practice in accordance with any exclusive system. (*Vote Transactions*, Vol. xix, p. 31.)

Resolved, That those gentlemen who desire to report on special subjects and will pledge themselves to report at the next meeting, be requested to send their names, and the subjects on which they desire to report to the Permanent Secretary. (*Vote Transactions*, Vol. xix, p. 42.)

Resolved, That hereafter the necessary expenses for rent of hall for general meetings and rooms for Sections to accommodate the annual meetings, and the necessary expenses for cards of membership, be paid out of the treasury of the Association. (*Vote Transactions*, Vol. xix, p. 42.)

Resolved, That each State Medical Society be requested to prepare an annual register of all the regular practitioners of medicine in their respective States, giving the names of the college in which they may have graduated, and date of diploma or license. (*Vote Transactions*, Vol. xx, p. 20.)

Resolved, That this Association recognizes specialties as proper and legitimate fields of labor.

Resolved, That specialists shall be governed by the same rules of professional etiquette as have been laid down for general practitioners.

Resolved, That it shall not be proper for specialists publicly to advertise themselves such, or to assume any title not specially granted by a regularly chartered college.

Resolved, That private handbills addressed to members of the medical profession, or by cards in medical journals, calling the attention of professional brethren to themselves as specialists, be declared in violation of the Code of Ethics of the American Medical Association. (*Vote Transactions*, Vol. xx, p. 28.)

Resolved, That a committee of one be appointed residing at Washington, to render the Librarian of Congress such assistance as the interests of the Association may require. (*Vote Transactions*, Vol. xx, p. 29.)

WHEREAS, The proper construction of Art. IV, Sec. 1, Code of Ethics, A. M. A., having been called for, relative to consultation with irregular practitioners who are graduates of regular schools.

Resolved, That said Art. IV, Sec. 1, Code of

Ethics, excludes all such practitioners from recognition by the regular profession. (*Vote Transactions*, Vol. xxi, p. 30.)

Resolved, That if any member fail to reply for more than one year to the circular sent to him by the Board of Trustees he shall forfeit his right to the volume, and it shall revert to the Association, to be sold to any applicant at the current rates. (*Vote Transactions*, Vol. xxi, p. 30.)

Resolved, That the Committee of Arrangements for the next ensuing meeting of this Association, and for all meetings thereafter, be directed to prepare a list of members present on a separate roll, for convenience and accuracy in calling the ayes and nays when the same shall be demanded. (*Vote Transactions*, Vol. xxi, p. 60.)

Resolved, That each year, until otherwise ordered, the President-elect and the Permanent Secretary be directed to appeal in the name of the Association to the authorities of each State where no State Board of Health exists, urging them to establish such boards. (*Vote Transactions*, Vol. xxvi, p. 50.)

Resolved, That the Permanent Secretary is hereby directed annually to report the names of States where boards of health exist, and also of those which decline to establish them; said report to form a part of the annual proceedings of the Association. (*Vote Transactions*, Vol. xxvi, p. 50.)

Resolved, That members of the medical profession who in any way aid or abet the graduation of medical students in irregular or exclusive systems of medicine, are deemed thereby to violate the spirit of the ethics of the American Medical Association. (*Vote Transactions*, Vol. xxvii, p. 48.)

Resolved, 1. That the American Medical Association adopts the International Metric System, and will use it in its Transactions. (*Vote Transactions*, Vol. xxx, p. 44.)

2. Requests that those who present papers at its future meetings employ this system in their communications, or reprints thereof. (*Vote Transactions*, Vol. xxx, p. 44.)

3. Requests the medical boards of the hospitals and dispensaries to adopt the Metric System in prescribing and recording cases; and that the Faculties of the medical and pharmaceutical schools adopt it in their didactic, clinical, or dispensing departments. (*Vote Transactions*, Vol. xxx, p. 44.)

Resolved, That the President and Secretary of this Association are directed to annually petition Congress to enact a law which shall permit every person engaged in a scientific pursuit to import for his own use, free of duty, any one book or instrument appertaining to his special pursuit. (*Vote Transactions*, Vol. xxx, p. 45.)

Resolved, That the above-named officers are further directed to urge the State Medical Soci-

ties and their auxiliary branches to aid this Association in accomplishing this purpose, by petitions to Congress, and by otherwise influencing Congressmen. (Vide *Transactions*, Vol. xxx, p. 45.)

Decision by Judicial Council: A gentleman who is not in affiliation with a County, District, or State Medical Society, where such organizations exist, is not entitled to be registered as a permanent member upon the claim of having been a delegate from a body not now entitled to representation in this body. (Vide *Transactions*, Vol. xxx, p. 57.)

Resolved: First, That a committee of five be appointed by the President of the Association, to be called the Standing Committee on "Atmospheric Conditions, and their relations to the prevalence of Diseases."

Second. That that committee be authorized to select such places as will best indicate atmospheric conditions in the more important climatic and sanitary districts of the United States—not less than six, nor more than twelve—and establish therein a means for continuous observation and record of all appreciable conditions of atmosphere, according to the most approved methods, and of the origin and prevalence of all acute diseases.

Third. That the Committee, through their chairman, be authorized to draw upon the Treasurer of this Association for such sums as may be found necessary for the proper execution of the work assigned to it, the aggregate amount not to exceed \$500, during the ensuing year, and that a detailed report of all sums drawn and expenditures made must be presented at the next annual meeting of the Association. (Vide *Transactions*, Vol. xxxii, p. 35.)

Resolved: That the regular graduates of such dental and oral schools and colleges as require of their students a standard of preliminary or general education, and a term of professional study equal to the best class of medical colleges of this country, and embrace in this curriculum all the fundamental branches of medicine, differing chiefly by substituting practical and clinical instruction in dental and oral medicine and surgery, in place of practical and clinical instruction in general medicine and surgery, be recognized as members of the regular profession of medicine, and eligible to membership in this Association on the same conditions and subject to the same regulations as other members. (See *JOURNAL OF THE AMER. MED. ASSOC'N*, Vol. viii, p. 722.)

Whereas, It has been the unwavering policy of the Trustees for the publication of *THE JOURNAL*, to enlarge and increase the value of *THE JOURNAL* as fast as the income of the Association will permit, therefore,

Resolved, That said Board of Trustees be a Standing Committee on Finance to which all

propositions for the appropriation of money, made hereafter, shall be referred and reported upon before final action on the same by the Association. (See *JOURNAL OF THE AMER. MED. ASSOC'N*, Vol. viii, p. 722, 1887.)

MEDICAL PROGRESS.

Therapeutics and Pharmacology.

PROFESSOR LIEBREICH'S REMEDY FOR TUBERCULOSIS.—LIEBREICH has given to the Berlin Medical Society an account of his newly proposed remedy which consists of cantharidate of potash—being 0.2 gram of pure cantharidin and 0.4 gram of potassic hydrate—in 20 cubic centimetres of water. He uses the remedy by subcutaneous injections, beginning with not more than one-fiftieth part of a decimilligram of the solution. The dose is gradually increased until one or two decimilligrams have been attained; it is likely that six decimilligrams will be found to be the maximum dose. The drug appears to affect diseased tissues only, and it may be applicable to other affections besides tuberculosis. Drs. Heymann and B. Fraenkel have made the clinical experiments thus far reported. They have no cures to report, but they have been agreeably impressed by the measure of amelioration in some of their cases and the absence of any untoward consequences. It has been found that expectoration has been increased, an effect which, as Liebreich infers, is due to the specific property of cantharidin to excite serous exudation from capillary vessels, especially in those that have already been the subject of morbid irritation.

Medicine.

ARTHRITIS BLENNORRHOICA.—DEUTSCHMANN (*Archiv für Ophthalmologie*) has observed a child three weeks old, with ophthalmia neonatorum, that later presented redness and swelling of the knee-joint. Gonococci were found in the secretion of the conjunctival sack in large numbers, and also in smaller proportion in a portion of the joint secretion obtained by exploratory puncture. The writer is of the opinion that the cocci were carried directly by the blood or lymphatics, from the conjunctival sack to the joint.

LEAD POISONING TREATED BY IODIDE OF IRON.—The following practical suggestion in *The Lancet*, for February 14, is quoted from a medical journal of Lille, full title not given, regarding the treatment of workmen in white-lead factories, who suffer from lead-poisoning. It is stated by M. Lavarand that he has found the iodide of iron, in the form of pills as prescribed in the French Codex, very efficacious in the above named condition. Sometimes he gives these pills

alone, at other times he combines the iron with the phosphide of zinc. Under this treatment, workmen who have already begun to show signs of plumbism were enabled to continue their occupation; their general health also improved, and the amount of hæmoglobin was increased.

Obstetrics and Diseases of Women.

OVARIOTOMY DURING PREGNANCY.—The *British Medical Journal* contains an editorial comment on the report of ENGSTROM, of Helsingfors, concerning seven cases of the above named operation, published in the *Annales de Gynécologie* for November, 1890. In two of these cases the ovariectomy was performed during the second month, while the other five ranged between the third and seventh months of gestation. All seven patients survived the operation, and with a single exception all went on their time of accouchment, giving birth to living children. In the exceptional case abortion occurred at the third month, and it is stated that she had aborted three times previously, early in gestation. In the course of the operation in this case the uterus was wounded, as the tumor was sessile. For some years past, pregnancy has not been held by ovariectomists to be a contra-indication to abdominal operations, since it has been found that such operations are not only not necessarily fatal, and that they do not of necessity result in abortion. In some cases there have been removed successfully cysts of large size or large solid tumors, the very gravity of the ovarian disease having been the incentive to the surgeon to undertake the operation, in order that by so doing the pregnant uterus might be liberated from its ovarian complication. On the other hand, a small tumor has been regarded as an indication to operation, since the progress of uterine evolution in pregnancy may involve a torsion of the ovarian pedicle and all its perilous sequels.

As to the method of operation in these cases, it is advised that the incision should be made high, and begin near the umbilicus, especially if the tumor lies high, so as to avoid as far as possible any excessive traction on the pedicle of the tumor. The uterus should be exposed as little as possible during the operation, since atmospheric contact is often an excitant to uterine contraction. A warm sponge should be made to cover the exposed surface during the time of the tumor's extraction. After the operation, a carefully adjusted bandage will ordinarily secure the healing abdominal wound against damage during the subsequent stages of gestation. Engstrom favors the removal of an ovarian complication of pregnancy whenever the diagnosis becomes clear, and he quotes the experience of Jetter to the effect that the tumor, if left alone, is liable to become a serious source of danger. Some of the worst cases of torsion of the pedicle have oc-

curred during pregnancy, and the fetus is in especial danger, not less than 48 per cent. perishing, either by a premature arrest of pregnancy or by accident during parturition. The statistics obtained by Engstrom in regard to the results of operation in these cases appear to show that not more than 20 per cent. was attended by premature delivery; and in some of these cases there was a wounding of the uterus in the course of the operation—and where this complication arises the presumption that the uterus will be evacuated is almost inevitable. It is not, of course, claimed that ovariectomy can be practiced in all these cases, as for example, in those patients where the tumor is large and lies low, occupying the pelvic cavity, and the uterus has already developed to a considerable size. In one such case, Engstrom induced labor at the seventh month, and afterwards removed the tumor.

Pathology.

SCARLATINAL CIRRHOSIS.—DR. SAUNDBY, of Birmingham, in the *British Medical Journal*, December 27, treats of some of the rarer forms of hepatic cirrhosis, such as the diabetic, rachitic and scarlatinal varieties. In regard to the last named variety, he thinks that a decidedly practical interest may be involved in it as a possible cause of those not very uncommon cases of cirrhosis met with at the post-mortem table in young children. Scarlatinal cirrhosis may be said to be known only to the pathologists, who have found it in the bodies of persons dead from the sequelæ of scarlet fever. The liver, in these cases, presents no abnormal change that can be recognized by the naked eye, but the microscope shows commencing new formation of fibrous tissue in the portal canals, fissures and spaces.

Ophthalmology.

PANOPHTHALMITIS.—DR. VÉNIDÉS, of Smyrna, (*Journal de Médecine de Paris*), Feb. 1, 1891, claims that early operative interference should be insisted upon in all these cases. He reports one case of exsiccation in a child a few weeks old, that was followed by recovery in a case apparently hopeless.

In adults he regards enucleation as the preferable procedure, while in children he thinks exsiccation should be employed. He altogether rejects sections of the optic nerve as it leaves a foyer of infection, that may lead to meningitis.

CORTICAL BLINDNESS.—FÖRSTER (*Archiv für Ophthalmologie*, xxvi, 1) offers the following conclusions from his observations: 1. The deviation of the line of demarcation toward the defective side, so often met with in homonymous hemianopsia, does not depend upon a mingling of the elements of both optic tracts in the retina, but upon the favorable vascular conditions of the point of sharpest perception in the occipital cor-

tex. 2. Bilateral hemianopsia is not necessarily connected with complete loss of function in both halves of the visual fields of both eyes. 3. The cortex of the occipital lobe governs the topographical ideas or conceptions, whether acquired by the sense of sight or the sense of touch, or by the consciousness of effected muscular movements, or by descriptions. If these portions of the brain become diseased, the power to grasp or to reproduce topographical conceptions is lost. 4. For color distinction, it is not enough that, with complete integrity of the retina, a small portion of the cortical region should be intact in its functions. The power to distinguish color is much more readily lost than the power to distinguish the shape of small letters, when the nutrition of the cortical elements is disturbed. 5. Destruction of the cortex in the occipital lobes does not produce atrophy of the optic nerves.—*N. Y. Medical Journal*.

DETERMINATION OF REFRACTION.—SCHWEIGER uses the phrase "illumination test" to describe the process of retinoscopy, or keratoscopy, or coreoscopy, because its essential purpose is to determine the optical value of the displacement of the illuminated field in the fundus of the eye, by revolving the mirror upon its axis. The test is of special value in the determination of strabismus.

Bacteriology.

TYPHOID AND PSEUDO-TYPHOID BACILLI IN RIVER WATER.—DR. CASSEDEBAT (*Annales de l'Institut Pasteur*, No. 10, October, 1890), following up Rietsch's work on the river waters of Marseilles, gives the result of an examination of seventy specimens of water from which 250 cultivations were made, with a view of determining whether the Eberth bacillus is to be found in the waters of the Durance which supply a part of the city where typhoid fever is endemic and often epidemic. In no case was he successful in finding the Eberth bacillus, but he was able to separate three bacilli—"pseudo-typhoid bacilli"—which resemble the typhoid bacillus in many respects; like it, they can all withstand the action of pretty strong carbolic acid. They all present clear spaces or deeply stained masses, which might readily be taken for spores; but they and the true typhoid bacillus containing these bodies are all killed at a temperature of a little over 45° C. They stain equally badly by Gram's method. They have a lateral and oscillatory motion as well as the forward motion. The plate cultivations are so much alike that unless all four can be seen together it is difficult to distinguish one from the other. On potatoes, in broth, and in milk, they are alike, except that they develop with different degrees of rapidity and vary somewhat as regards the alkalinity and acidity of their products at the end of about thirty days, and also as to the degree and time of appearance of the

turbidity produced in broth. There are differences, however, to be observed in these organisms grown in broth or milk to which small quantities of the various aniline staining reagents have been added. The ordinary cultivation methods are sufficient to distinguish these four forms from ten others (a list of which is given in the paper) for which the typhoid bacillus has at times been mistaken. None of the pseudo forms are quite so toxic to white mice as the true form, and one of them is quite innocuous. Although Cassedebat was not able to find the true form in water taken from the water supply which was most open to contamination, he found that this was not because bacilli could not live in water, as in distilled water, to which a cultivation had been purposely added, he could easily distinguish its presence at the end of forty-four days, and when added along with half-a-dozen other forms he could find them at the end of seventeen days. He comes to the conclusion, therefore, that the true typhoid bacillus does not occur in water so frequently as is sometimes represented, and that one or other of the forms of pseudo-typhoid bacilli has in certain cases been mistaken for it.—*British Medical Journal*.

MEDIA FOR CULTIVATION OF TUBERCLE BACILLUS.—SIR HUGH BEEVOR, at a recent meeting of the Pathological Society of London, read a note on "Media for Cultivation of the Tubercle Bacillus." The results he had obtained showed how diverse might be the media that could be employed, and how wide the variations of temperature in which the bacilli would grow. His observations on potato cultivations agreed with those of other observers—that the growth was very slow, there being from twenty days to a month before the first sign of growth appeared. It was stated that cultivations on the potato for three generations did not diminish the virulence of the organism. He found that the bacilli grew in broth to which glycerine had been added at a temperature lower than they did on potato or in glycerine agar-agar, and he showed tubes which had been kept at a temperature not exceeding 60° F. Bacilli cultivated in glycerine agar-agar to which corrosive sublimate in the proportion of 1 in 200,000 had been added were hindered slightly in their growth. This proportion of perchloride when compared with the average body weight of a man equalled from five to six grains. The demonstration of the wide range of temperature at which the organisms would grow was interesting in suggesting that their habitat was probably wider than had been supposed. Dr. Crookshank said that the paper had involved a very great amount of labor, the growths being very slow and requiring constant watching. The results of inoculation of animals with these subcultures when published would prove of great interest.

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 68 WABASH AVE.,

CHICAGO, ILLINOIS

All members of the Association should send their Annual Dues to the Treasurer, Richard J. Duglison, M.D., Lock Box 1774, Philadelphia, Pa.

LONDON OFFICE, 57 AND 59 LUDGATE HILL.

SATURDAY, MARCH 28, 1891.

THE ABUSE OF THE FOOT.

This humble member may be likened, mechanically, to an arch of five single boulders of unequal size. The abutments are the calcaneus on one side and the metatarsi on the other, and the thrust which the load on the astragalus exerts on these two points is equalized by the plantar muscles and fascia. As a matter of fact, like the triangular bridge at Croyland, the foot has more than two points of support. The posterior haunch of the arch of the foot is the calcaneus alone, but the anterior haunch divides first into two, then into four, and then into five branches. Not only does the load on this arch vary from moment to moment, but almost every *voussoir* is subject to strains in many directions from tendons or muscles attached to it. The resultant of these varying factors is a living equilibrated polygon, a living arch.

In every movement of the knee there is a corresponding change in this subtle arch, as may be demonstrated by the reader by crossing one leg over his knee. To go a little further, changes in the position of the body in any direction are followed by related changes in the form of the foot. It is not only modified in its form by momentary exercise, but its growth and development follow the needs of the body which it supports. To reverse the comparison, the supple, graceful foot makes healthful exercise and graceful activity a possibility. The undeveloped or unhealthy foot is a cause of bodily and mental disease, as we shall attempt to show.

The anthropomorphia and children, in walking,

turn the outer edge of the sole downward, their feet being better adapted to climbing. In the untrammelled foot of the youth the hallux is quite opposable, and the whole foot is muscular and expressive. This expressiveness and sympathy with the ground, we sometimes see in bathers and in base-ball players, whose feet are properly dressed. It is manifested in a coördination of muscular action, which, beginning in the contact of the feet with the earth, is reflected up through all the muscles of the body to the face.

Unfortunately, our civilization is in the prohibitive stage. The feet of our children are encased at an early age in unyielding boxes. The muscles of the sole are arrested in their development, and the subtle foot is made into an unyielding stump. The circulation in the extremity is impeded during half the day, and during the time when it is called into greatest use. The ligaments and bones fail to develop symmetrically from restrained function and inadequate nutrition. As a result, when the burdens and emergencies of life fall upon the unfortunate victim of civilization, sprains and dislocations are of frequent occurrence. Nor is the arrest of development noticed in the plantar muscles only; it is, on the contrary, felt in all those muscles of locomotion which are called into play in graceful walking, and are unused in stumping about on the stilts fashion prescribes. Especially is the *tibialis porticus* undeveloped, and as the load on the astragalus increases with the weight of the body, the resultant of all the forces on the bones of the foot determines "a joint of rupture." This is more often brought about by the coincident stretching of the plantar fasciæ, supporting the arch, by the use of shoes which bring them in contact with the soffit, or under surface of the arch. As soon as the shoes grow old, or when they are exchanged for loose, flexible slippers, the plantar fasciæ drop to a straight line again, and the abutments of the arch separate so far that a joint of fracture appears, usually at the top of the arch. Thus results that most serious and refractory condition called flat foot.

It must not be supposed that flat foot is to be applied to those conditions only in which the plantar arch is wholly collapsed. Almost as painful conditions are to be observed where the plantar fasciæ have been stretched only enough to allow all or most of the strain to come on the ligaments

of the joints. This strain gives rise to a traumatic inflammatory process, which has been termed by GOSSELIN "tarsalgia" of the young adults. It results in a muscular immobilization of the foot on account of the pain. Then follows, as a consequence of the vascularization of the bones, a melting together of the joint surfaces, and, at last, bony union in the segments of the arch. This process requires years of suffering.

The method which prevails in foot-wear is responsible for this fearful condition, and it is aggravated by the habit which prevails in schools of having children stand in classes for a long time. Shopkeepers, and bookkeepers, and mechanics who have to stand long in tight shoes, are apt to acquire the condition. Among dentists it is easily noticed in one foot more than the other. The diagnosis is made by the symptoms, by the form of the foot, and by the track which the bare foot makes on paper.

The treatment is mechanical and preventive. The former may be read in the literature, but we should like to call attention to the latter for the benefit of posterity. Children should not wear our box shoes, but a flexible, loose, moccasin-like slipper with no heel. The shoes of young people should have added a stiff heel and a stiff half-sole, nothing more. The constriction of the ankle and instep should be avoided, because it results in interference with the nutrition of the foot.

So small a matter can hardly receive too much attention when we see how necessary are sound feet to exercise, health and happiness. In the fierce struggle for existence which is now upon our race, survival will depend on the application of intelligent attention to little matters. The prejudice of custom and fashion ought not to taboo the scientific discussion of any subject, not the least important of which, is the normal development of the foot.

IS CANCER A PARASITIC DISEASE?

The analogy, in many respects, of the malignant tumors to those infective diseases, such as tuberculosis and leprosy, which have been shown to be due to the presence of microorganisms, has naturally suggested to pathologists the possibility of a similar cause, and in 1887 SCHEUERLEN, published an account of a bacillus which he had found in cancers, and which he believed to be

the *materies morbi*. Similar observations have since been published by others, but his views do not seem to have met with very wide acceptance. More recently, attention has been called to other bodies occurring in cancerous tumors, which have been thought to belong to the lowest order of animal life. DARIER, in 1889, described a parasite occurring in Paget's disease of the nipple, which he believed to be a coccidium—a member of the order of sporozoa. ALBARRAN, THOMA, WICKHAM and SJOBRING have since then reported observations of the same kind, although THOMA does not commit himself as to the nature of the organism. Finally, RUSSELL has published in the *British Medical Journal*, an account of what seem to have been very painstaking investigations on what he considers a characteristic organism of cancer. He demonstrates it by staining the sections with fuchsin, decolorizing in water and alcohol, and then staining with iodine green for contrast. The bodies in question retain the fuchsin stain, which is removed from the other tissues. They are minute, spherical bodies, surrounded in many cases, by a transparent capsule, and apparently propagating both by spores and buds. RUSSELL, although he believes them to be identical with some, at least, of the organisms described by previous observers, is disposed to think them of vegetable nature, belonging to the sprouting fungi, of which the yeast plant is the most familiar example.

They were found in forty-three out of forty-five cases of cancer of different organs, often in great numbers. In non-cancerous tissues they were found five times in over fifty cases. In three of these, owing to the presence of ulcerating surfaces, the author thinks there was a probability of infection, which might ultimately have developed the cancerous character. Of the other two, one was an adenoma of the breast, the other a gumma of the meninges.

DR. RUSSELL's conclusions have been called in question in various quarters. EHRICHSON considers the bodies described to be cells in a condition of hyaline degeneration, and gives drawings which seem to tend to confirm this view. CATTELL finds that bodies presenting much the appearance of those described and figured by RUSSELL may be produced by the presence in the staining solution of minute drops of the aniline

used in its preparation. On the whole, at the present time, the probabilities seem rather against the parasitic nature of the bodies in question. A theoretical objection to any parasitic hypothesis might be raised from the fact that, although carcinomata usually resemble, in their histological structure, the epithelium of the tissue in which they originate, metastatic deposits develop with the same structure as the original tumor. This would appear to favor the view that the infecting elements are the cells of the tumor rather than a foreign organism. In view of the doubt as to the interpretation to be put on the appearances, cultivation experiments seem desirable.

SURGERY OF THE GALL BLADDER.

SIR SPENCER WELLS, in his Bradshaw lecture, recently published, presents a review of the status of modern abdominal surgery, in the course of which he refers to the operations that are now done on the liver and gall bladder. He admits that many successful cases are on record of removal of gall stones and subsequent closure of the gall bladder by sutures, as well as of fixing it to the abdominal wall and forming a fistulous opening, but he is strong in his opinion, expressed first about five years ago, that an excision of the gall bladder, or cholecystectomy, is the preferable practice. He says that he can almost foresee that the general rule for future surgeons will be to expose the gall bladder, empty it with a syringe, raise the liver, protect the stomach and intestines by sponges, tie the cystic duct, with two ligatures, divide it between them, separate the gall bladder from the liver by knife or scissors, and then close the abdominal wound.

RESUSCITATIVE EFFORTS IN THE NEW-BORN.

When it is stated by an authority of eminence that, "I believe the attitude of the profession, in general, is one of incredulity, as regards the efficacy of the means at our disposal to restore the life of children in the more desperate cases of asphyxia. In my experience it is the usual procedure to spank the child, to immerse it in hot and cold water, and then to wrap it in warm clothes and place it by the fire to die. Yet the object of medical practice is to save life, and for my part I regard the rescuing of a new-born infant from impending death to be as distinctly a

professional triumph as the saving of life by ovariectomy, by Cæsarian section, or by the operation for appendicitis," it becomes the bounden duty of the profession to turn for a moment to a due consideration of the statement, and a thought—or more than thought—of the real possibilities of reducing the number of still-births. We can scarcely agree with the author in believing that the resuscitation of the still-born is to be regarded as an achievement of equal greatness as the conserving of a *developed* life by the surgical procedures above named; yet the importance of rescuing an infant life—where two lives are not in immediate peril—is not to be determined by a comparison. It is clear that if well-directed and patiently-continued efforts will restore life in a goodly number of still-births, then the professional course to pursue admits of no discussion, but does call for more elucidation, a wider and deeper interest, and a continued investigation with a view of both limiting the known causes of still-births, and the perfection of those methods will the more readily insure the return of viability to the one whose spark of life was supposed to have departed.

EDITORIAL NOTES.

CURIOUS SPELLING.—The *Albany Medical Annals* prints a list, received from one of the governmental departments at Washington, showing 169 ways in which the word "pterygium" was spelled—157 attempts in the singular, and 12 attempts in the plural form of the word—in reports to the department from "boards" consisting of three graduates in medicine.

EXTREME ANTISEPTIC VIEWS OF LEOPOLD.—At Prof. Leopold's obstetrical *clinic* but one vaginal examination is made—except in pathological cases—and the examiner must first pass through a veritable antiseptic mill. First, the operator must have a general bath and fresh clothing, then a cleansing, rubbing and scrubbing, with brush, soap and water, of the hands and arms for a period of five minutes—being accurately timed during the operation. This is followed by a brushing for three minutes with a sublimate solution 1:2,000. Everything is then removed and the process of brushing and cleansing is again repeated, this time with a 1:1,000 sublimate solution. After this the hands are to be kept im-

mersed in the antiseptic solution until the patient is ready, when *one* finger may be quickly passed into the vagina. Prof. Leopold really deprecates *any* vaginal examination in normal labor, giving it out that, "The ideal childbeds are those in which no vaginal examinations have been made."

TYPHOID FEVER GERMS IN MILK AND WATER SUPPLY.—Two very interesting and professionally instructive examples of the communication of typhoid fever through contaminated milk and water have lately been added to the record we already have along this line of research. In both instances the outbreak was quite widespread throughout the given district, and careful investigation clearly brought out the exact source of the contagion, and the means of its dissemination. One point appears to be quite certainly indicated by these recurring examples of the spread of this fever, viz., that in typhoid fever the question of a physical resistance to the influence of the poison does not play so important a part as may be the case with other affections. In other words, the essential principle of typhoid does not seem to be a more or less constant factor of our environment; therefore, when it is forced within the circle of extrinsic influences any resisting power is insufficient to its overthrow.

BIRTH-LIST OF CHICAGO.—The completed returns for 1890 place the total number of births at 20,878; number of males born 9,813; number of females 9,452; number of twins 221; and one case of triplets. This proportion of twin and triplet births does not agree with that observed in foreign countries. It is stated that the proportion of triplet births in Saxony is as 1:1,000, in Russia as 1:4,054, in Ireland as 1:4,995, and in England as 1:6,720.

A NEW USE FOR OLD BARRACKS.—Application has been made to President Harrison for the appointment of a commission to visit the abandoned army posts of Southern Colorado and Northern New Mexico with the view of selecting the best site for a National Retreat for Consumptives. It is claimed that the climate of the sections mentioned is probably the most favorable we have for those afflicted with serious lung troubles.

GOLD AND MANGANESE IN TUBERCULOSIS.—Dr. John Blake White read a paper upon the use

of gold and manganese, subcutaneously, before the Medical Section of the N. Y. Academy of Medicine, February 17th. While the writer does not claim any specific action for this method of treatment, yet—as with Drs. Shurly and Gibbs—the results have been very promising in a number of cases. Marked improvement has occurred in cases having detailed histories of phthisis. A number of physicians spoke upon this occasion of having observed the good effects mentioned by the author, and upheld the moderate claims put forth. A further outcome is awaited.

RESULTS OF INTUBATION OF THE LARYNX.—Dr. J. Mount Bleyer, of New York City, gives in the *Archives of Pediatrics* an analysis of five hundred and twelve cases of intubation with the following results: "Out of 251 cases of children under three years of age, there were 73 recoveries, and in 260 cases three years of age and over, there were 115 recoveries; total, 189 cases out of 512 operated on." The causes of death are given throughout. The greatest number died from sepsis (39), broncho pneumonia (40), pneumonia (41), diphtheritic bronchitis (67), bronchitis (45), heart failure (21), exhaustion (20), double pneumonia (16), and membranous croup (12).

MEDICAL ITEMS.

PROGRESS OF STATE MEDICINE.—A Bacteriological Laboratory has been established in connection with the Ontario Board of Health, with Dr. McKenzie in charge.

A POOR FIELD.—Scott County, Kansas, has but one physician, and he is now compelled to leave because of the following conditions: but one natural death has occurred during the past year; obstetrical cases and accidents happen but infrequently; and the atmosphere is so pure, and the people so generally healthy, that even an ordinary living cannot be made by one practicing the healing art. The population of the county is given at 1,260.

HANDY SURGICAL DRESSINGS.—Dr. Clinton B. Herrick (*N. Y. Med. Jour.*), in a paper on "Railroad Surgery" advises that each "caboose" and baggage car carry a packet containing splints and antiseptic dressings of a simple nature, and so labeled that any man of ordinary intelligence would be able to apply them in case of accident. He argues that it would render the condition of

the injured more comfortable, and his wounds less liable to become septic, until the aid of a surgeon could be had.

REPORTS OF THE ILLINOIS STATE BOARD OF HEALTH.—The medical press generally appear to appreciate the leading position taken by the Illinois State Board of Health in the matter of a higher standard of medical education. The *Boston Medical and Surgical Journal* says: "These publications of the Illinois State Board are an important factor in the gradual improvement which is taking place in the medical colleges."

THE VIRCHOW TESTIMONIAL is assuming large proportions. The seventieth birthday anniversary of this great man occurs on October 13, 1891. The form the testimonial is taking seems to be wise and enduring, viz., a large gold portrait medal to be presented to Professor Virchow himself, while bronze replicas of the same will be given to members of his family, and to a certain number of scientific institutions.

THE CONSTANT BACTERIA OF MILK.—Over forty different varieties of bacteria have been isolated from a specimen of normal milk. They are grouped into classes, and their varied actions produce the changes ordinarily taking place in milk, as well as the extraordinary chemical effects produced under peculiar and unusual circumstances. It is not gainsaid, however, that "foreign" bacteria are not concerned in the uncommon chemical changes.

SUMMER SCHOOL OF MEDICINE.—The Medical Department of the University of Virginia has decided upon the establishment of a summer session, beginning July 13, and continuing two months.

JEFFERSON COLLEGE'S NEW SURGEON.—At a meeting of the faculty of Jefferson Medical College on March 9, H. Augustus Wilson, M.D., was elected Lecturer on Orthopedics in the Jefferson Medical College, and surgeon in charge of the Orthopedic Department of Jefferson Medical College Hospital, vice O. H. Allis, M.D., resigned. Dr. Wilson is professor of General and Orthopedic Surgery in the Philadelphia Polyclinic and College for Graduates in Medicine, surgeon and medical director to the Polyclinic Hospital, lecturer on Orthopedic Surgery in the Woman's Medical College, and was formerly

pathologist to the Presbyterian Hospital, and one of the surgeons at St. Mary's Hospital. He is a fellow of the College of Physicians, and of the Philadelphia Academy of Surgery, member of the Philadelphia County Medical Society, and the Medical Society of the State of Pennsylvania.

WOMEN PHARMACISTS IN NEW YORK.—It is stated that there are over one hundred women pharmacists in New York City, not one of whom, however, maintains an independent business.

TUBES FOR KOCHINE.—An order has been placed with a German firm of glass manufacturers for one million tubes of particular form and extra quality of glass, to be used for the general distribution of the now famous "lymph."

ST. LOUIS MEDICAL SCHOOLS.—About 280 diplomas will be given out in St. Louis this month.

A WOMAN'S HOSPITAL FOR MEMPHIS.—A Woman's Hospital Association has been organized under the laws of the State of Tennessee, the object of which is the erection of a properly-equipped hospital at Memphis for the treatment of deserving poor women and children.

MEDICAL TRAINING FOR WOMEN.—Official notice has been given of the admission of women to the Edinburgh Royal Infirmary, under certain conditions which are embraced under six different headings.

INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY.—The seventh meeting under this title will be held in London on August 10-17, with the Prince of Wales as president.

TENTH GERMAN CONGRESS FOR INTERNAL MEDICINE is to be held in Berlin immediately following the Surgical Congress, or from April 6-9. Professor Leyden, of Berlin, will be president. Very interesting discussions will take place, prominent among which, of course, will be the Koch treatment.

SPRING IS WITH US.—March 2, the Medical Department of the University of Louisville conferred the degree of M.D. upon one hundred and fifty candidates.

THE LIBRARY OF THE NEW YORK STATE MEDICAL ASSOCIATION now contains about 8,000 volumes, and 5,000 pamphlets.

TOPICS OF THE WEEK.

CANTHARIDINATE OF POTASH IN TUBERCULOSIS.

Last week's meeting of the Berliner Medizinische Gesellschaft was of exceptional interest. Every place in the hall was filled in expectation of Professor Liebreich's address on his new remedy for tuberculosis. The following is an abstract of the address, some of the principal points being given in the Professor's own words. He began by saying that, though it was not his custom to publish a research the results of which he had not investigated in detail, he felt obliged, by the special circumstances of the case, to do so in this instance.

He gave an account of the principles that had guided him in this and similar researches. Years ago, in his first address on chloral hydrate, he had already pointed out that, in considering a substance, it is of the greatest importance to form a notion of the atomic grouping in the molecule. The observation of this principle led to the discovery of a number of efficacious remedies—for instance, salicylic acid and salicylate of soda. "How long substances can remain unemployed is shown by the example of chloral hydrate, the therapeutic qualities of which were unknown for thirty-seven years after its discovery by Justus von Liebig."

But it would be considered to be led only by the above principle in research. An illustration of a different method is the discovery of lanolin, by which ointment therapeutics, which had sunk almost into contempt, were raised to a scientific basis. "Then again—and this we owe to Koch—disinfectants were made the objects of inquiry. From the beginning I expressed my opinion that all those substances that exercise a deleterious influence on the lowest organisms outside the body must be inefficacious when introduced into living tissue. In continuation of my former chloral researches, I was able to show, in connection with the 'dead spaces' in chemical reactions that the reaction that takes place in the cell is very different from that which takes place outside of it."

Then, again, Pasteur's theory that bacteria are destroyed by their own products of metabolism was followed up; but the extremely toxic quality of these products has hitherto formed a hindrance to their efficacious therapeutic action. It is to be hoped, however, that the attempts to extract efficacious bactericidal substances from the products of metabolism of the bacteria may yet be attended with success. At present, treatment by attenuated bacterial cultivations is forming the subject of many experiments, but this has no direct relation to pharmacodynamic investigations.

Professor Liebreich then turned to his experiments with local anesthetics, named by him *anesthesia dolorosa*, because though they produce local anesthesia, the injection itself is painful. In the course of investigations with these bodies, it became clear that their effect was not due to chemical action, as in the case of chloral hydrate, but to purely physical causes. It was while engaged in these researches that Professor Liebreich first saw lupus cases which were being treated by tuberculin, and at once formed the opinion that the local action must

be due to a substance, whatever its origin, similar in action to those known under the name of "acria." Upon this the speaker's experiments with cantharidin (the active principle of the Spanish fly) were begun. The Spanish fly has been used occasionally in therapeutics since the time of Hippocrates; Pliny mentions it. In later times it occurs in France and Italy under the names of "pastilles galantes" and "diabolini," but its effect has always been uncertain, often dangerous, owing to the impossibility of dosing the active principle with any accuracy.

It was Robiquet who first extracted the active principle, cantharidin, as a chemically pure crystalline substance, which can be weighed and dosed with exquisite accuracy. Its toxic qualities, and especially its irritating action on the kidneys and urino-genital apparatus are well known, and have been described by Cornil, Ida Eliaschoff, and others. When cantharidin is taken internally serum is exuded from the capillaries, not only of the kidneys, but also of the lungs and of other organs, as has been proved by the experiments of the speaker. This is the characteristic action of cantharidin. According to the speaker's theory, the irritability of the capillaries varies in the different parts of the organism. He assumes that an irritated condition of the capillaries favors the process of exudation. Thus a dose of cantharidin, too small to exercise a toxic action on healthy capillaries, will produce exudation in inflamed capillaries. The exudation of serum in tissue may act in two ways, 1, by nourishing the cells and bringing back to their normal condition badly nourished cells; and 2, by the disinfecting action of the serum the affected spot.

In his experiments, which he began at the Augusta Hospital, the speaker made use of a solution containing cantharidinate of potash. The maximum dose was 6 decimilligrams, the usual dose being from 1 to 2 decimilligrams. "If it can be proved that in cantharidin we possess a means of producing an increased secretion of serum at any one spot, we may succeed in concentrating at this spot efficacious substances, which, under ordinary circumstances, do not easily find their way there. We know substances that circulate in, and are decomposed by the blood, but which only with difficulty pass through the capillaries. But if we know that at an affected spot the exudation from the capillaries is facilitated, we can imagine that a larger quantity of an efficacious substance may find its way to this spot, thus strengthening the otherwise feeble disinfecting power of the serum. It seems to me not unlikely that such a combination of two remedies might possibly lead to a new therapeutic method. As regards practical application, special attention should be paid to the kidneys. It is clear that this treatment should not be applied where there is disease of the kidneys. I should advise doses of 1 decimilligram to begin with, followed by an experimental increase to 2 decimilligrams. It is as well to let a day elapse between the injections."

On the conclusion of the address Dr. Heymann and Professor B. Fraenkel exhibited cases treated by cantharidinate of potash, which showed marked and in some cases surprising improvement. Berlin Correspondent.—*British Medical Journal*.

TEMPERANCE MEDICAL MEN IN ENGLAND.

Whatever may be said of total abstinents from alcohol, it can never be alleged truthfully against them that their peculiar habit interferes with their industry, their energy, or their perseverance. When an aspiring member of Parliament is about to contest a district, one of the first things he considers is the strength of the teetotal element. If there be many teetotal organizations, he is sure from the first that he must reckon with them; they will have their own ideas, they are likely to combine in many ideas, and perfectly certain it is that, should they set to work, their physical powers will fully compensate for any shortcomings of an argumentative kind. They will be aggressive, patient, vigilant, and of long endurance. Last week there was an illustration of some of these faculties in those abstaining members of the profession of medicine who are the representatives of the British Medical Temperance Association, a medical body now numbering close upon 500, and, we believe, over-numbering that figure if they who are learning their "rudiments," as Dr. Cophagus called it, may be considered medical. This Society, like its fellows, meets ordinarily in its own central rooms in the west end of London, or in the central rooms of its branches in other parts of the Kingdom, and there carries on its work of papers and discussions. But now, on the suggestion of its indefatigable honorary secretary, Dr. Ridge, the members of the Society, with characteristic pertinacity, are moving into new pastures and holding meetings in different districts, in order to invite the busy practitioners of the district visited to meet them in the most convenient way, and discuss with them the great argument for and against alcohol. On Wednesday week last, February 25, the first meeting of this kind was held at Northampton House, St. Paul's-road, Highbury, and for numbers present, as well as for the matter of debate, it must be accepted as a most successful first attempt. Dr. B. W. Richardson, the President of the Association, occupied the chair, and in an opening address led the way simply towards discussion. Every word that was extreme was avoided as unnecessary. The apathy of the profession as compared with the energy of the clergy was first touched upon, and then the sanitary side of the matter was made a special point for consideration. Alcohol produces a certain large and calculable mortality; the mortality means a large bill of sickness, and the sickness means an enormous loss of labor and the rewards of labor. But we, as a profession of health, said the chairman, are the custodians of health, and ought, therefore, specially to concern ourselves in the wholesale removal of the preventable cause of so much disease and misery. If an epidemic from some more obscure cause destroyed a tithe of people so systematically and regularly as alcohol does, we should be ambitious to vie with each other in discovering the mode of reaching and removing the root of the evil. It is our duty to do the same thing in regard to this great plague which is always before our eyes. Another point dwelt upon was the recognizable pathology of alcohol, and the lesson it supplies, in respect to the employment of it as a medicinal remedy. Touching this last subject, the speaker repeated his often stated

opinion that alcohol, who never it is prescribed and is used, should be prescribed as "a weapon of precision"—that is to say, diluted with water in measured doses, without the least complication. This plan, he urged, answers perfectly, and after fifteen years' employment of it he had found it equal to every requirement. Finally, the requirement itself was, he thought, in truth, very much curtailed when all the facts of the necessity were fully disclosed. The masters of physic who recognized the force of the *experientia fallax* were most sound when they exposed that kind of experience, and never more was that soundness verified than in the practice of alcohol administration. Let a practitioner, said the speaker, who has been accustomed to use alcohol, once have the courage to look at the other side of the shield, and see what remarkable results follow treatment without it—as, for example, in cases of hemorrhage, pneumonia and asthenia, and the rapidity with which the mode of treatment without alcohol would advance would lead to quite a revolution in the practice of using alcohol as a remedial instrument. Dr. Ridge, Dr. Norman Kerr and Mr. Moir followed on the same side. The most trenchant opponent was Dr. King, who dwelt more particularly on the social influence of alcohol for good when perfect moderation tempered appetite. He was of opinion that wine, judiciously taken, aided the worker and sustained the enfeebled. Altogether, this new experiment of local discussion on the alcohol topic from its medical aspects, by medical men amongst themselves, was so friendly, hopeful and instructive that we trust it will be repeated. It is good for brethren to dwell together in unity.—Editorial, *Lancet*.

CHOLERA INTELLIGENCE.

According to intelligence up to the end of January last, cholera had undergone a great diminution in Syria, no new cases having been recorded for several weeks in the villayets of Aleppo, Adana, and Damascus. On the other hand it was reported that two cholera deaths had occurred in the villayet of Diarbekir and five in that of Beyrout. The total cholera mortality in Syria up to the week ending January 24, had been 4,170. Of these, the villayet of Aleppo was responsible for 2,361, that of Damascus for 1,189, of Beyrout for 421, of Adana for 97, of Memouret-ul-Aziz for 85, and of Diarbekir for 15. Later intelligence is to the effect that cholera had ceased in Syria by January 22, and we have information from a correspondent who is able to speak with considerable authority, to the effect that so far as the towns, at least, of Beyrout and Damascus are concerned, no new case of cholera has as yet appeared. It may also be added that quarantine restrictions imposed at Constantinople on arrivals from Syrian ports between Alexandretta and Beyrout have been removed, and that the Syrian ports generally are regarded as free from the disease. There is, however, reason to believe that, as regards Tripoli cases are being hushed up, and that the disease has not yet quite ceased there. The serious epidemic in Japan, to which we have from time to time adverted, also seems to have come to an end.—*The Lancet*.

PRACTICAL NOTES.

TÆNIA.

Thomson speaks highly of the following :

- R. Chloroformi, ℥j.
Syrup simp., ℥j. m℥i. ʒj.
S. Take in three equal doses at 7 A.M., 9 A.M., and 11 A.M. At midday give ℥j of castor oil.

—*Le Courier Médical*, March 15, 1890.

Another combination is :

- R. Flor. Koosso, ʒiis–ʒiv.
Ext. filic. mar. ʒeth., ℥jiss–ʒij.
Aque destillat., ℥jij. ʒj.
S. Take in three portions half hourly.

—*Kinder-Arzt*, April, 1890.

After a light diet the evening before, give the following on an empty stomach :

- R. Ol. tigilii, gtt. j.
Chloroform, purif., ℥j.
Glyceriu., ℥j, ℥jij. ʒj.
S. Take in two doses, half an hour apart.

—*Pharmaz. Zeit.* 45, 1890.

SUMMER DIARRHŒA.

The following is recommended :

- R. Resorcin, gr. iss–gr. iij.
Infus. chamomil, ℥jij.
Tr. opii., gtt. ij.
Tr. cascarril., gtt. xv. ʒj.
S. Teaspoonful every two hours.

—*Kinder-Arzt*, April, 1890.

Critzmann employs the following :

- R. Bismuth, salicylat., gr. xv–ʒss.
Tinc. opii., gtt. j–v.
Infus. Therac., ℥jij.
Syrup rubi, ℥v.
Rum, ℥iv–v. ʒj.

ASTHMA.

- R. Tinct. stramonii, ʒj.
Tinct. lobelie æther., ʒj.
Potass. nit., ʒj.
Sp. æther nit., ʒss.
Tinct. aurant recent., ʒss.
Aq. chlorof., ʒvi. ʒj.
S. Take two tablespoonfuls at bedtime, and one tablespoonful if difficulty of breathing comes on.

TREATMENT OF SPASM OF THE GLOTTIS.

Sir Morell Mackenzie, an acknowledged authority in laryngeal cancer, recently imparted to his brethren of the Laryngological and Rhinological Association an item of practical information, which we communicate to our readers in the hope that it may come in handy just when something handy is a desideratum. The successful treatment of that alarming and dangerous condition, spasm of the glottis, is oftentimes difficult

and uncertain, but Sir Morell tells us that by setting up a rival reflex, the laryngeal spasm, itself a reflex, usually due to peripheral irritation, may be overcome *instantly*. All one has to do is to get the sufferer to take a pinch of snuff or pepper, or, failing either condiment, to excite sneezing by tickling the mucous membrane of the nares. The immediate result is a paroxysm of sneezing, after which the patient sinks quietly back to sleep, breathing like a newborn infant. The treatment is logical as well as practical, and as it is now made public for the first time, it is well worth a trial.—*Ex.*

ACUTE ECZEMA AND IRRITABLE CONDITIONS OF THE SKIN.

Dr. J. V. Shoemaker (*Times and Register*), advises :

- R. Cocain. hydrochlorat., gr. iij.
Atropine sulphat., gr. j.
Morphine sulphat., gr. ij.
Unguent. acid. carbolici, ʒj. ʒj. *

PIGMENTATION OF PREGNANCY.

- R. Cacao butter, ʒjss.
Castor oil, ʒjss.
Zinc oxide, grs. 45.
Oil of rose, q. s.
ʒj. Sig., to be applied morning and evening.

ANÆSTHETIC MIXTURES.

The following formulæ for the preparation of the anæsthetic mixtures, are given in the *Medicinische-chirurgische Rundschau*. The A. C. E. mixture, according to this journal, is made by taking :

- R. Alcohol, 1 part.
Chloroform, 2 parts.
Ether, 3 parts.

Another method of making it is to use :

- R. Alcohol and ether, 1 part.
Chloroform, 3 parts.

With some the anæsthetic mixture is made by adding 4 parts of chloroform to 1 part of alcohol.—*Medical News*.

ARISTOL FOR FISSURED NIPPLES.

Vinay, in *Lyon Médical*, has recommended the employment of aristol in the treatment of fissured nipples occurring during lactation. He uses it in cases in which there is much ulceration and pain. The mixture is as follows :

- R. Aristol, 1 drachm.
Liquid vaseline, 5 drachms.

This is to be applied to the breast and carefully wiped off before the child nurses. After its employment the pain diminishes and cicatrization goes on rapidly. In cases in which the glands become much involved, this preparation of aristol may be rubbed into the enlargements with advantage.—*Medical News*.

SOCIETY PROCEEDINGS.

Gynecological Society of Boston.

217th Regular Meeting.

The Gynecological Society of Boston held its 217th regular meeting at No. 19 Boylston Place, Boston, on Thursday December 11, 1890, at 4 o'clock P.M., with the President, W. SYMINGTON BROWN, M.D., in the chair.

DR. AUGUSTUS P. CLARKE read a paper entitled
THE INFLUENCE OF THE POSITION OF THE PATIENT IN LABOR IN CAUSING UTERINE INERTIA AND PELVIC DISTURBANCES.

(See page 432.)

DR. WM. G. WHEELER said that common custom influences the position of the patient or the time of labor, but each case should be treated according to its own merits. The Irish physicians use the knee elbow position. He prefers the left lateral position but does not feel like recommending any particular position exclusively.

DR. C. E. PRIOR stated that most women select their own position and in his own practice he allows the patient to do so. He doubts whether the long continued position is responsible for the many results alleged. He feels that the sooner the patient is delivered the better, and he would rather use the forceps early than allow troublesome delay. He said the reader did not touch upon the subject of position to rectify presentation. On this subject he is not as enthusiastic as a certain writer whose article appeared about a year ago.

DR. D. WALDO STEARNS said that he had the same opinion as the last speaker and he believes that too long labor is responsible for many evils. The patient should walk about during the first stage in order to keep up the pains which stop if the patient lies down. In the second stage he prefers the left lateral position. If there is inertia he gives 15 grains quinine according to the teachings of Fordyce Barker; this is usually very effective. Friction over the abdomen may also be applied. If there is still no progress he then uses the forceps. The urine should be drawn and the bowels evacuated unless there has been an operation within a short time. He gives an enema in the first stage. He prefers the use of forceps to turning. Can the physician prevent rupture of the perineum? Some authorities say that ten per cent. are unavoidable. He does not have as many cases of rupture as formerly. He forces up the head when necessary. He has recently read an article which advised the occurrence of a rupture if necessary to save the child from too long delay.

DR. BROWN could recall no case he had seen in which the position of the patient made any difference. He prefers the left side. The patient

should walk about during the first stage but not enough to get tired. To relieve tiresome aggravating pains he administers an opiate and thinks it preferable. He would not use forceps until absolutely certain that labor would be too long delayed if they were not used. He has seen the perineum torn several times but believes that it can frequently be saved by the method explained by Dr. Stearns, which he also has used. Changes in position are recommended. He does not like to give much ether and would use it only just as the head is coming out. He fears post-partum hæmorrhage after the use of ether.

DR. WILLIAMS has had the same experience as Dr. Stearns. He thinks the position should be changed. Some of the effects may be due to something of which we do not know. He has used chloral with much benefit.

DR. JEFFERSON has experienced no trouble from any one position long continued, and he fears too speedy delivery more than this.

DR. ELLIOT prefers the left position and he changes if necessary. He remembered one patient who would not lie down, and the head of the child was found to be blocked. He has used chloral and opium, but would rather feed the patient, which he thinks prevents tardy labor. He stretches the perineum and holds back the head and thus rarely gets a rupture. Sometimes gives stimulants.

DR. COOK treats the bowels before labor sets in, but he finds it difficult to get his orders carried out. He prefers the action of chloral to opium. He has seen good results from the use of hot water douches by rectum or vagina. He prefers the position on the left side because manipulation to save the perineum by the fingers in the rectum is easier thus. He would not allow one position too long in the second stage. If the os remains rigid after three or four hours he would not allow labor to go on without treatment.

DR. IRISH said he never saw any mischief arise from the use of one position, yet he felt that too long delay in one position may cause trouble. He would use instruments if after three hours there was no advance and there were sufficient pains. He prefers chloroform to ether. He never had any post-partum hæmorrhage result from the use of anesthetics. He does not continue the administration until there is complete anaesthesia. He thinks it acts as a stimulant to pains.

DR. WHEELER narrated a case of complication which he had not seen for forty years before. It is unique in his experience. He has seen one case complicated with measles which did well and another with scarlet fever from which the patient died. The peculiar case was one of cerebrospinal meningitis. The woman was 28 or 30 years old. First labor. She had the disease for twelve hours before labor. Dr. W. saw it with

another physician, who said he had a patient with rheumatism. There were pains in various parts of the body but no labor pains—no increase of temperature—no heat or swelling. The uterus was quiet—eight hours later there was more pain—no vomiting. The os uteri seemed to be a little more patulous and dilatable. Thought the pains to be neuralgic and gave an opiate. Then noticed some spots on the abdomen which did not disappear on pressure. The whole skin was sensitive. He urged dilatation as he felt that something was coming. He ruptured the membraues and the pains subsided. The labor was terminated in about eight hours. When the uterus began to act the other pains ceased for about twenty-four hours, when they came on again and the spots became more pronounced. There was some rigidity of the muscles of the neck. Both typhoid and meningeal disease were thought of. Next day the head drew back and the patient died in seventy-two hours. He had never met with such a case before.

DR. PRIOR stated that he uses the forceps to deliver a difficult case if the head is low down, but he turns it if it is high up.

The President, DR. W. S. BROWN, said that he prefers the position on the left side. He does not allow too long a delay in labor, but advises and uses forceps or some other method of interference.

DR. CLARKE, in closing the discussion, said that he has felt like giving food during labor but he found he had been criticised for such advice. He has had cases of labor which came to a speedy termination after a change of position.

Philadelphia County Medical Society.

Meeting of February 11, 1891.

(Abstracted from THE JOURNAL.)

THE TREATMENT OF CORNEAL ULCERS BY THE ACTUAL CAUTERY.

DR. G. E. DESCHWEINITZ, read a paper having the above title. After rehearsing the history of the use of the actual cautery in cases of corneal troubles the writer brought his own cases, in which this method of treatment had been used, together under the following several heads: 1. Small central ulcers in children of bad nutrition, which either through neglect or imperfect treatment have tended to form an abscess. 2. Shallow central ulcers in serofulous patients, the ulcer having a slightly turbid base, very chronic in its course, and declining to heal under ordinary remedies; in all of the cases of this character there were the appearances of former granular lids, and in one active trachoma. 3. Phlyctenular ulcers, beginning in the form of small pustules at the corneal border, speedily ulcerating

and surrounding themselves by a yellow area of infiltration, and with a strong tendency to perforate. 4. Infecting or sloughing ulcers associated with pus in the anterior chamber, or, in other words, hypopyon keratitis. 5. Marginal ring ulcer, or that form which is sometimes seen in purulent ophthalmia, occurring just at the circumference of the cornea, often covered up by the chemotic conjunctiva, and very likely to perforate, because it is hidden by the swollen tissues and not observed. 6. Herpes of the cornea, one being an example of an ulcer associated with herpes zoster ophthalmicus, and the other true herpes of the cornea in which a vesicular eruption occurs, breaks down, and leaves an ulcer; that form which has been seen under the same circumstances, as when herpes occurs around the lips and nose.

In all cases the cautery had only been used after other methods of treatment had been tried, and the author says that he has not one single bad result to record. In three out of thirty cases perforation of the cornea took place, "with evacuation of the aqueous humor, twice as an accident during the application of the cautery, and once when the ulcer had nearly perforated, and Desce-met's membrane had bulged forwards, forming its floor, then I deliberately burned through the tissue."

As to the method of application, a small Paquelin thermo-cautery, a galvano caustic loop, or, as in the writer's experience, a platinum probe heated to redness in a Bunsen burner, may be used.

The pupil is atropinized or eserized—according to the indications present—and a few drops of cocaine are instilled shortly before the operation. The lids are then separated by the operator, and the cautery applied gently to all of the sloughing material. Usually but one application is required, yet subsequent touching may be demanded. The after-treatment does not differ from that given to an ordinary corneal ulcer; and as to the cicatrix, or leucoma, resulting it is no more extensive—the author holding that it is even less so—than happens when healing from other means. There are some contra indications to this use of the actual cautery, among which are "extensive ulceration, involving a large area of the cornea," and yet in "just such cases very good results have been obtained." It should not be used in an ulcer which has already perforated, and where anterior synechia has occurred. And it does not seem to the writer to be indicated in cases of hypopyon keratitis where "there is a large ulcer associated with a hypopyon that nearly fills the anterior chamber, and in which it can be demonstrated that the collection is exceedingly tenacious, having assumed the character of a slough."

In the discussion which followed, DR. EDWARD

JACKSON said he had but a comparatively small experience in the use of this method. He felt convinced that heat was the only antiseptic which would penetrate as far as the tissue was involved, yet while it does so, and destroys the suppurative process, it also destroys the corneal tissue leading to a corresponding opacity. In his experience scraping of the surface of the ulcer, together with the use of eserine, had been sufficient.

DR. CHARLES H. THOMAS had not used the cautery, having found that a thorough wiping of the ulcers, and touching with the solid stick of nitrate of silver, to have answered very well.

DR. SAMUEL D. RISLEY, also, had not used the cautery, although aware of its merits. He had found other measures to do, excepting in some cases in which failure had been met. In such cases, hereafter, he felt that he would resort to the cautery treatment.

In closing the discussion, DR. DESCHWEINITZ said: "The actual cautery should not be used, as a rule, until the ordinary and milder methods have been employed. If the cautery is applied carefully, and not, as recommended in some text books, beyond the edge of the ulcer and into the healthy tissue, and only that portion of the structure burnt which would be destroyed by the process of disease, there will be no more opacity of the cornea than if it had not been applied. In certain types of infecting ulcers, with a creeping tendency, it seems to me there should be no delay in the employment of this most potent remedy."

SEVERE PUERPERAL ECLAMPSIA; THE IMMEDIATE INDUCTION OF LABOR; RECOVERY.

A few remarks, together with a very complete history of a case, were offered by DR. WILLIAM H. MORRISON. The medicinal measures, which had been found of value, were rehearsed, and the unsettled etiology of the disease was reviewed. The primary indication in puerperal convulsions happening previous to delivery, viz., the speedy termination of the pregnancy, was emphasized; and meantime the convulsions should be controlled by the use of ether, chloroform, chloral and other similar substances. Also was relief to the kidneys to be afforded by free catharsis and diaphoresis. The writer felt that in the more severe cases, where uterine contractions were tardy, and a rapid termination of the pregnancy, in consequence, impossible, that the question of the removal of the fetus by abdominal section should be seriously considered. "Such a course would in a few minutes remove an important causative factor in the production of the disease, afford a better opportunity for the action of remedies intended to control the paroxysms, to stimulate the action of the kidneys and to favor the excretion of poisonous matters, and probably give, both to the mother and to the child, the best chance for life."

DR. REYNOLDS WILSON said he simply wished to refer to the use of morphia in the treatment of puerperal convulsions. He had recently seen its clinical use by Professor Winckle, who advocated its administration hypodermically in doses of one-half grain, repeated in from four to seven hours, and continued until three grains in all had been given.

DR. WILLIAM S. STEWART had seen a number of cases of puerperal convulsions, and never found any difficulty in controlling them by the use of chloral, which he found acted decidedly within a specific length of time. "One drachm of chloral injected into the rectum will control the convulsions for about one hour and a half, almost to the minute." It may then be repeated. The effect is profound sleep, and the action of the drug will be manifest, it is stated, in ten seconds.

DR. WILLIAM H. WELCH mentioned a case in which chloral had been freely used, yet the patient was not saved.

DOMESTIC CORRESPONDENCE.

Results with Koch's Remedy.

To the Editor:—I desire to give my results with Dr. Koch's remedy in a short communication. I may say that the same has been used in my private institution for diseases of the lungs and throat since December 23, 1890, in twenty-two cases of pulmonary tuberculosis, some of them having also laryngeal tuberculosis, and in one case of lupus vulgaris of the face. These cases were reported and shown to the Buncombe County Medical Society, March 2.

From the beginning I determined to avoid general reactions, and we kept the temperature records to preserve us from over-dosage rather than to assure us that the patient is showing therapeutic effects in the symptoms produced. I find that local reactions can frequently be observed with the stethoscope by examinations in from two to thirty-six hours after an injection, and that local reactions occur in the larynx and in the lupus case, as well as in the lungs, without material rise of temperature, or the production of general symptoms.

I find further that all the cases which I have selected for the Koch method, in both early and advanced stages, but particularly in the former, show an unmistakable general improvement, consisting in gain of flesh, from three to fifteen pounds (one advanced case gained ten and one-half pounds in three weeks), there is an increase in strength, a better cough, less cough and better sleep, the patients are thoroughly conscious of their improvement. Also that in the majority of

cases local changes have occurred in the affected parts, which, without Koch's method, we have always recognized to be for the better. These local changes consist in the disappearance of moist sounds, gurgles, râles and crepitations, and the reappearance in their stead of a better character of respirations; in the larynx of diminution of swellings and infiltrations, cleaning off and granulation of ulcerations; in the lupus case, of progressive healing and repair, and with these improvements we have less cough and expectoration.

In four cases the symptoms have entirely disappeared, and microscopically, the bacilli fail of demonstration, or are comparatively few and gradually diminishing in number where we still get sputum for examination.

In my local examinations I find that all tubercular deposits do not react to the remedy at the same time. Virchow and others have shown anatomically that the very young tubercle, the miliary eruptions, and the old deposits located in fibroid and cicatricial surroundings are frequently unaffected, and I explain these evidences by the vascularity of the tissue surrounding the tubercle, being least, or entirely non-vascular, where we find a given dose of the remedy inoperative. Later local reactions occur in recent deposits to even smaller doses than formerly were borne without local reaction, because by the natural changes these tubercles have undergone in the intervening time, vascular and granulation tissue has been produced, and the tubercle is now accessible. Older deposits react locally only after reaching large doses, because of the slight and feeble circulation through cicatrizing connective tissue, not enough of the remedy could previously reach them to produce an effect. The local reaction of accessible tubercular tissue is in proportion to the dose, and if excessive, causes not only necrosis of the tissue, but so rapidly that I have seen the excavation and an almost entire upper lobe in less than a week, at one of the Hospitals in Berlin. Such rapid processes bring with them the dangers of general infection.

In considering our results, we have of course to remember that some improvements would have occurred, the same as we have witnessed heretofore, due to climatic and other influences, and particularly due to the strict and correct management of cases in a well conducted institution. We had, a year ago at this writing, not a single case in our establishment that was not showing some improvement, but I believe I am not mistaken in my belief that under Koch's method we have had a more uniform and more rapid favorable influence to record than heretofore, and in some cases, so much so that we cannot but attribute it, at least to a considerable degree, to the action of the remedy.

Our dosage begins with half a milligram, and

an increase by half milligrams every second or third day, and only then when we are entirely satisfied that to the last two doses no general or local reaction has occurred. Any rise in temperature at all attributable to the remedy is a signal for a delay of an additional day in repeating now a smaller dose. After ten milligrams have been reached we increase by two or two and a half milligrams, and we have now, in some cases, arrived at forty milligrams without ever having disturbed the subjective feelings of the patient, and with the happiest results.

Seeing these results so satisfactory, and knowing that nowhere in this country or in Europe a similar method of administration has been adopted, I believe it my duty to call attention to what I believe to have been a system of over-dosage with production of poisonous and dangerous symptoms in the use of the remedy.

CARL VON RUCK, M.D.

Asheville, N. C., March 3, 1891.

The Philosophy of Consumption.

To the Editor:—A proclamation by an eminent physician that he has discovered a specific cure for consumption in its most prevalent and insidious form, known as tuberculosis, might well create a deep and universal interest, since there are comparatively few of us that do not have this deadly enemy within the limits of our cousin kinship. And if German slaughter-house statistics are to be taken as representative, no less than ten per cent. of our domesticated-horned cattle, are a prey to the same disease, though seldom discovered during life. This fact would suggest that tubercular consumption is still more prevalent in the human family than has yet been supposed, and that many carry it under the cover of other maladies.

But unfortunately for any hope for a specific remedy, the preponderance of evidence points to the fact that consumption is much more a product of individual habits and social and climatical conditions, than a resultant of any one agency. Indeed, the positive evils may vary not only in their degree, but also in their number and order of action in the period of its evolution.

If it were hereditary in the sense that it is transmitted by the blood, as a specific germ or virus, then the offspring of consumptives would have an attenuated form of the disease which, by reasoning from analogy, ought to secure them exemption from any further danger along that line. Such, however, is not the case. But if we say a special fitness is inherited, then we can understand how the offspring of consumptives are prone to develop it, since they are not only born with hereditary qualifications, but not infrequently they are cradled amidst the very agencies

which fostered the evil in their parents, if indeed, they were not primarily causative.

That the contribution of heredity to consumption is great is undoubtedly the case, and more than any other factor it would seem to have a directing power in the army of inducing evils. But the fact that the greater number of the offspring of consumptives escape the disease, even where the general family resemblance is quite pronounced, is readily explained by the difference in personal habits, the circumstances of different periods or the domestic regulations instituted by medical counsel. Also the fact that consumptives so frequently spring from neurotic parentage and the victims of dissipation, especially alcoholic, still further goes to show that the hereditary element is essentially a reduced power of resistance to formative evils, and that as a negative condition, it may hold the balance of power in focusing the forces. Thus, heredity in disease can be understood as in no sense implying a specific force, but rather, as an atonic or susceptible condition, varying in its precise character and producing a *pars minoris resistantie*, or a special weakness in a special way.

That the germ bacillus does not originate consumption, there can be no doubt, unless consumption is not to be regarded as a disease until it is full fledged, for otherwise, the germ would be present in the earlier formations, as well as the later, which, according to good authority, is not the case. But that this parasite has a special affinity for consumptive tissue, there is no question, and that it thrives therein with great rapidity, hastening retrogressive changes, is also to be granted. But as yet, this is all we are entitled to believe.

We thus see that the lines of successful treatment must be both constitutional and local, that the constitutional cannot be specific and the strictly local cannot be curative. The constitutional must be of a negative and positive character, having regard to the support of the healthy remnant, and which will require correction of any deficiency whatsoever in order to remove the morbid constitutional habit. The local will be cleansing of the affected organs from the germs and morbid products.

The evident selective affinity of Koch's lymph for tuberculous tissue may enable it, in certain cases, to effectually seal the arterial capillaries about the affected organs, owing to the intense vaso-motor disturbance produced. This would starve the germs, which with the tubercular matter, may be expectorated through the moisture and motion of the lungs. In incipient cases the tubercles might be as readily absorbed as catgut ligature, and the germs, if any, fall to phagocytic prey. The Koch lymph is evidently not a poison to the germs, and probably has no other action on the affected organs than that of an irritant,

having a selective affinity, by virtue of the kishity with its contents. This theory of its action is supported by our common knowledge of the power of pyogenic agents to awaken old or slumbering inflammations, and the fact that septic fevers, such as small-pox, have been known to leave the consumptives in the last stages free from every symptom.

J. S. CHRISTIAN, M.D.

148 Washington B'ul., Chicago.

Cases of Typhoid Fever in Infants.

To the Editors.—It is commonly thought that typhoid fever is rare in young children. Perhaps this is so, yet so far as I have observed, it is not much of a respecter of persons, for in my experience it has ranged through all ages. The following cases it may be proper to state:

Some years ago my wife took this fever while nursing a child 6 months old. This child became sick with the disease the same day and, though separated from her parent, ran a course *pari passu* with her mother. When one had a good day the other did, and when one had a bad day the other followed suit. It was not till the end of three weeks that there began to be signs of improvement. But both began to improve the same day, and so went on. For two years afterwards both were alike subject to occasional attacks of stomatitis. When nearly 3 years old, the child died of diphtheria. Its mother then took the diphtheria, but had it lightly.

The second case was 9 months old, and was also a nursing child. In this family there were nine children from 14 years down, and all had the fever. The mother also had the fever and was in the family way with her tenth child. I did not discover that she was any the worse for being pregnant, though she was well worn down by care before she took the fever. They all recovered. In due time the mother was confined. The child, however, was smaller than any of the others. I had an interest to know whether this child had the fever *in utero*, and so rendered insusceptible to the fever afterwards; but at the age of 3 years it died of croupous diphtheria, and so closed my interest in the case. The father, who had had the fever in the army, escaped. It was plain that they were all exposed to the same cause—filthy water from a tank filled by wash in which were dead rats.

In another family of six children, they and their mother had the fever, except the youngest, then 1½ year old. It was not nursing.

These examples rather hint that it may not be so much due to difference in constitution of young children that they should be measurably exempt from typhoid, as to their less exposure to the ordinary sources of the cause. As a rule, they

move in narrower spheres than older children, and so are less exposed and less liable to be affected; while, if they are nursing mothers who come down with the fever, they are exposed and take the poison point blank, and do not escape.

Is there any record of the case of an infant who was nursing its mother when she came down with the typhoid fever, that did not also take the disease? If not, this shows the great danger to families, if cows from whom they receive their milk happen to be affected with the fever, examples of which have been reported.

E. CHENERY, M.D.

Boston, Mass.

BOOK REVIEWS.

A TREATISE ON RHEUMATISM AND RHEUMATOID ARTHRITIS. By ARCHIBALD E. GARROD, M.A., M.D. (Oxon.), M.R.C.P., etc. With charts and illustrations. Philadelphia: P. Blakiston, Son & Co. 1890. Chicago: A. C. McClurg & Company. Pp. 342. \$6.00.

To the student of medicine—be he either upon the threshold of the great science, or treading faithfully along those sacred grounds which a life time's toil has gained him access—this classical treatise will find a warm interest. And he who has the "love of learning" in his heart will but bewail the interruptions of professional duty which call him away ere "finis" proclaims that all has been said. It is really unfortunate that professional exactions prohibit the resolve—which comes when such a lucid delineation of a disease process so widely observed as rheumatism is placed before us—to closet one's self for a day, or a night, that the mind may arise to a full conception of quite all there is to know upon the subject in hand. Few there are thus blessed. Yet for those who run, the moment's halt they must needs have will find refreshment between the covers of this volume.

Starting out with a clearly written history we have, following a review of the theories heretofore advanced with relation to the pathology of rheumatism, which the author concludes with this statement:

Time alone can show whether or no any of the above-mentioned observers have succeeded in discovering a microorganism which is the actual specific cause of the phenomena of rheumatism. Until then, we can only rely safely upon the results of clinical study, which seem to indicate that, in spite of the difficulties presented by the apparently constitutional nature of the malady, no theory of the pathology of rheumatism which has as yet been advanced makes so good a show of explaining the peculiarities and variations in the prevalence and type of rheumatic attacks, or accounts so satisfactorily for the peculiar distribution of the local lesions of the disease, as does that which attributes them to an infection from without.

Then appear clear, terse chapters upon the etiology of rheumatism, and the association maintained with other bodily affections, going into the subject quite to the uttermost, and yet without that redundancy of expression which so often mars a study of this nature.

The first part of the treatise ends with a résumé of the treatment of rheumatism as it stands to-day, and shows the strong position held by the salicylates.

Part II (Book II) treats of rheumatoid arthritis, and is a comprehensive exposition of the leading thought of the times.

A voluminous bibliography, and a very complete general index, closes the volume.

The reviewer cannot well take leave of this book without also noticing the publisher's work, which is, in few words, much superior to that usually observed.

ASSOCIATION NEWS.

Notice to Secretaries of Sections.

To the undersigned Secretaries of Sections are urgently requested to send the list of Papers to be read before their respective Sections, as soon as completed, in order that there may be no delay in the printing of the Programme of the Meeting.

C. H. A. KLEINSCHMIDT, M.D.,
Local Secretary.

3045 N St., Washington, D. C.

SPECIAL CORRESPONDENCE.

Shall The Journal be Removed to Washington?

THE ACTION OF THE MEDICAL SOCIETY OF THE MISSOURI VALLEY.

The following resolution was unanimously passed by the Medical Society of the Missouri Valley, in session at Omaha, Neb., March 20:

WHEREAS, It having come to the knowledge of this Society that an effort is being made to remove the headquarters of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION from its present location in Chicago to Washington, D. C.; Therefore, be it

Resolved, That we, the Medical Society of the Missouri Valley, instruct our delegates to the coming meeting of the American Medical Association to use all honorable means to retain the headquarters of said Journal in its present location.

F. S. THOMAS, M.D., Sec.

Council Bluffs, Iowa, March 21, 1891.

To the Editor:—I have been waiting patiently to hear the arguments that our Eastern friends rely on to effect the removal of THE JOURNAL to Washington. I have been impressed with most of them as applying with increased force to Chicago.

Leaving out the question of politics, there appears to be nothing in this agitation. But the fact that the next meeting of the Association will occur in the city that is a candidate for the location of THE JOURNAL renders it

necessary to thoroughly canvass the merits of the case before a vote is taken.

There is always a large attendance of the local members of the profession wherever the meetings are held. Washington, Baltimore, Pittsburgh, Philadelphia, New York and other Eastern and Southern cities will be more largely represented than they would be if the meeting were to be held in some other section of the country. Ought the vote of the members who chance to be present at the Washington meeting to decide this question, instead of a vote of the whole membership?

Should any meeting held in Washington or Chicago settle a dispute between these two cities? Undoubtedly the modesty and sense of fairness of our Washington brethren would forbid their participation in such a scheme.

There are the best of reasons to believe that the removal of THE JOURNAL would deprive it of a large share of those requesters to success that have contributed to make it the peer of any American medical journal.

When the loss of advertising patronage is mentioned, some of the advocates of moving for the sake of a change reply that THE JOURNAL should get along without advertisements. Very well. When Grant proposed to take Richmond did he tell his soldiers that they should get along without biscuit and bacon, or coffee? Have these gentlemen ever tried the novel experiment of publishing a journal without advertisements? Which one is so philanthropic as to give bond to indemnify from the loss?

A good certainty is better than an unreasonable, sentimental uncertainty.

It is not surprising, since THE JOURNAL has passed the experimental stage and is an assured success, that a clever neighbor should covet the promising prodigy, but it is too late, gentlemen, to ignore the labors of those who made it what it is.

Who is there in Washington who would have done better, under the same experimental circumstances, than have Drs. Davis, Hollister and Eggleson in an editorial capacity, and Mr. White in his able and courteous management of the important business and mechanical department of the enterprise?

Can we afford to repudiate those who have built up, and are improving our plant, sacrifice our best-paying advertisers, and move out of this great centre of population, commerce and wealth, with its vast accumulating libraries, universities and nine medical schools, with its army of about 2,000 under-graduate and post-graduate medical students?

Is it expected that the mere fact of publishing THE JOURNAL within the city limits of our Capital, is to exercise great influence over our representatives who go there periodically to make laws? In other words, has it become necessary to have editors and publishers performing the rôle of lobbyists to accomplish the ends of our great Association?

If a change must be had, for the sake of a change, St. Louis would be a better location for THE JOURNAL than Washington.

S. S. BISHOP, M.D.

Chicago, March 14, 1891.

To the Editor:—I have read most of the letters to THE JOURNAL, pro and con, in relation to the moving of the same to Washington, D. C., and I have not seen any opinion, as yet, coming from the profession in the old Granite State. But I am sure, that as I have consulted with my confères thus far, a united voice will come from her hills and valleys: "Let THE JOURNAL remain where it is, unless you wish to asphyxiate its present life powers!"

My reasons are the following: As far as I can judge, there are three to one of the members of the Association, regardless of location, who are opposed to its removal. It is much better and safer policy to let the majority rule in the make-up of all organized bodies. If for no other

reason, organic law will decide "Let it remain in Chicago."

That city affords the best location for it of any city upon this Continent, at the present time. I spent some four months there during the last season, and I know whereof I write. I took some little pains, while there, to investigate the past and present condition of the city; and I wrote several letters, which were printed in one of our local county papers, in regard to the city's development during the past fifty years. It is the most wonderful city upon this Continent. It puts all other cities in the shade as a business centre, when you combine its commercial and railroad facilities, even New York itself. While the latter city has 25 main lines, Washington has 3. Chicago has 35 through lines, running to all sections of the great West, upon which 1,500 to 2,000 trains run in and out of the city every day. Then its population of 1,200,000 makes it the second city in this Nation in numbers. In every form of mechanical, industrial and mercantile growth it is most wonderful. She to-day possesses 30,000 industrial shops and factories, has an area of almost 400 square miles, and if it increases in population for twenty years to come as it has in the last decade, it will become the Queen City of the World, larger than Ancient Babylon, Modern Paris, or British London.

It is argued that Washington is the best location on account of its superior advantages in medical men and literature, and this will serve to make the personnel of THE JOURNAL of a higher order. But I say Chicago leads all other cities in this country (save New York) in advantages for medical instruction. She has five chartered medical colleges, all in a most healthy and prosperous condition, keeping pace with all the wonderful and amazing developments of the other departments of the city.

I am not aware that our profession has any more lofty mountain peaks in medical erudition, or scholastic qualification, in Washington than in other medical centres.

Another plea for its removal—that because our Association is a National body it ought to be in Washington, as that is the National Capital. This may seem patriotic and theoretical, but who shall say how long Washington may remain the Capital of this Nation? The West is making great strides in population and increase of States, and soon the voice of this Republic may be heard in its vote to change the location of its Capital, and put it in a more central position. The vote of the people will rule this country, and that portion east of Washington, D. C., is but a fragment, in point of territory and population, compared with Northwest, West and South of this fast growing Republic.

It is for the very reason that Washington is the Capital, and the great centre of *political demagoguism and partisan strife that it should be the very last place to select for the home of THE JOURNAL.* It is the medium through which the sentiments of all medical writers are voiced from all sections of the Union, and it should not be placed where there is danger of its becoming colored in the least with *political predilections.*

Let our noble and ancient profession, stand upon its own broad, scientific character, and its intrinsic worth, to the best good of humanity. Keep it sacredly free from all foreign influences that can belittle its value in the estimation of the world.

For these reasons, and I could cite more if time and space would permit, I shall vote *not* to change the present home of our popular and well managed JOURNAL.

W. B. PORTER, M.D.

Walpole, N. H., March 14, 1891.

To the Editor:—I am opposed to the movement to change the place of publication of our National Journal from Chicago to the City of Washington. I think there is no valid reason for it: THE JOURNAL is ably conducted, centrally located geographically, and a

large business city like Chicago is much more conducive to the support and advancement of a medical journal than a *political rookery* like the city of Washington. I think our western members would have just cause for complaint if it were removed farther East. S. LAUGHTON, M.D.

Bangor, Me., March 15, 1891.

To the Editor:—As several good reasons have been and can easily be advanced why THE JOURNAL should not be removed, and no good reason has yet been given why it should be removed, and since no medical journal has ever yet flourished at the Capital, I cast my vote in favor of THE JOURNAL remaining at Chicago.

E. H. M. SELL, M.D.

44 West 49th St., New York, March 17, 1891.

To the Editor:—My best wishes for the continued prosperity of THE JOURNAL. I hope it may long remain in the great City of the Lakes. W. W. KEEVES, M.D.,

Supt. State Lunatic Asylum.

Austin, Tex., March 17, 1891.

To the Editor:—I can see no reason why the location of THE JOURNAL should be changed from where it now is and has been so long published, and as I believe, to the best interests of the Medical profession. Chicago is nearer the centre of the United States, and why remove THE JOURNAL? I think it far better for the Medical profession to advocate less change in our associations, rules, and regulations, and stand firmly together as a band of brothers and from upon all movements to create "isms" and "cisms" that tend to weaken and destroy the old landmarks of the profession. C. R. EARLEY, M.D.

Ridgway, Pa., March 17, 1891.

To the Editor:—I notice one of the reasons given by a subscriber for moving THE JOURNAL to Washington, is, that "We the official representatives of the profession should keep as closely to the Government as possible."

The people is the Government, and as Chicago is the centre of the people let THE JOURNAL remain in Chicago and move the Capital near to THE JOURNAL—that the centre be less top-sided. E. F. CLAPP, M.D.

Iowa City, Ia., March 21, 1891.

To the Editor:—Please put me down as in favor of retaining THE JOURNAL at Chicago.

A. B. JUDSON, M.D.

New York City, March 21, 1891.

To the Editor:—It is sound doctrine in medicine, as in other pursuits in life, to let well enough alone. THE JOURNAL has passed its minority, and is now full grown and is second to no journal published. Its financial success has grown with its years and it is now on a sound basis; its editorials are concise and to the point; its selections good and of the latest published. THE JOURNAL is in a healthy condition. It requires no medication or change of climate, to sustain its vigor and usefulness.

Let it remain in Chicago. B. L. HOVEY, M.D.

Rochester, N. Y., March 21, 1891.

A REPLY TO DOCTOR COMEGYS' LETTER.

To the Editor:—I see by the last issue of THE JOURNAL, that my erudite friend of Cincinnati, Dr. Cornelius G. Comegys, has evidently made an Herculean effort to convince the members of the American Medical Association, that their journal should be transplanted from Chicago to Washington, D. C. But like many other persons, who have unfortunately got on the wrong side

of great National problems, it has required a prolonged and gigantic effort on the part of the doctor, to convince even the most unsophisticated member of our Association that his position was right, or that his arguments were well founded and his logic unassailable.

The doctor seems to have forgotten that when THE JOURNAL was born, some seven years ago, that there was only 1,000 members of the Association, which limited its income to not over \$5,000 a year, plus the scanty returns it received from its advertising patronage, which at that time was less than \$1,000 a year, thus limiting the entire income (provided every member and patron paid up his subscription and advertisements promptly, which is seldom the case), not to exceed \$6,000, whilst the expense of publishing alone, not including any pay for editorial work, was over \$8,000 a year or \$2,000 in excess of the annual income.

But by being "so conservative, so determined, to take no risks that involved a prospect of pecuniary embarrassment" the management has increased the membership of the Association from 1,000 or less to over 5,000 members and subscribers, which guarantees an annual income of at least \$25,000 a year besides the annual receipts from its advertising patronage of about \$10,000, or a total of about \$35,000 a year. The management has bought and paid for their own plant and equipment for publishing, binding and mailing THE JOURNAL, and has done all this within the short space of seven years; and yet by this extreme care of the financial and business interests of THE JOURNAL, which Dr. Comegys condemns, and by which he says it "has been kept too much in the rear of the line of a contest for the due rank of medicine in communities and in the State;" yet, notwithstanding all this, it has risen from the cradle of journalism in this short time to a place second to none among the medical journals of the United States and Canada; and publishes more pages of reading matter each issue than any journal in our country, and over 400 more pages annually than any medical journal on the Continent.

From THE JOURNAL and its management proper he next turns his "old smooth bore" on the editorial qualifications of the organ of our Association, and says, "no one doubts the editorial capacity of Dr. N. S. Davis or Dr. Hollister, but these gentlemen, both are large practitioners," and because they are both industrious practical men, who are familiar with the every day work of the profession, and in sympathy with the ups and downs of the daily routine of the physician's life, and from experience know what he needs, he claims they are disqualified to edit a practical journal, for the practical doctors of the United States. Did mortal man ever hear of such an innocuous untenable argument? Does Dr. Comegys flatter himself, for a moment, that there is one out of every ten members of our Association who would or could be induced to believe that because a doctor is in the actual practice, and really a *practical physician or surgeon*, that he is therefore disqualified for the position of "Supervising Editor" of a practical journal for practical doctors?

Does any person suppose for a moment that if Dr. Comegys was seriously ill, or any member of his family, that he would employ such a physician as he would recommend for "Supervising Editor" of our journal to treat him or his family? "Not by a jug full." He would obtain the very best practical physician or surgeon he could get, because he was a *practical man* and not an impractical theorist. For the same reason the members of our Association want a *practical* physician at the helm of the Editorial Department, as well as a *practical* man at the head of the Business Department of THE JOURNAL, because they are *practical* and *know by experience*, what they are doing and talking about.

Our association has no use for high-flying theorists at the head of the Editorial Department of THE JOURNAL, who would fain weave gauzy editorials out of fine spun theoretical yarn, which to the innocent student, or unso-

plicated, might appear like a brilliant mental effort, but which to the everyday practical physician would be about as useful as sounding brass or a tinkling cymbal, as compared with food, in a time of famine.

In the preface of the first volume of Prof. Agnew's "Surgery" you will find this eminent surgeon saying: "Most of the pages have been written not in what may be termed moments of leisure, but during the hours of the night—hours stolen from the time usually allotted to the repose of body and mind, and after the daily labors of an exacting public and private practice." This sentence alone explains why the best physicians and surgeons of our country as well as of foreign lands so eagerly sought this most valuable work. Because it was written by a *practical* surgeon and not by a theoretical tyro in the medical profession; and yet in the face of all this our erudite friend would advise changing the practical physician and surgeon we now have for "supervising editor," for one who was *not* in the active, practice, and who would "promise and swear" that he would never enter the practice of medicine while he swings the editorial pen of our popular Journal. Now, Doctor, how long would such an editor retain the confidence and respect of the members of our Association? The hollow echo answers: "How long?"

The absurd idea that THE JOURNAL must be moved to Washington to obtain a place in the Cabinet is ridiculous. The farmers were but recently represented in our cabinet, but I have no knowledge that a single one of them left his farm and moved to the miasmatic flats of the Potomac in order to secure this recognition recently granted by the federal government. Then why should we remove our Journal there to obtain the same recognition?

In speaking of the consciousness of Chicago as compared with the perception of Washington we desire to ask the Doctor if he was conscious of the fact, that Washington only had *three* railroads, which it is absurd to compare with Chicago with more railroads than any other city in the world? We will ask the Doctor if he is conscious of the fact that notwithstanding the extreme consciousness of Washington, that there is not a journal—either medical, religious, scientific, agricultural or of any other nature—that has prospered or attained a national reputation that was or is edited and published in Washington? Doctor, are you conscious of the fact that there is not a daily paper published at present, or that ever was published in Washington that has, or ever had a real good local reputation, saying nothing of a national reputation? Are you conscious of the fact, Doctor, that even the *Index Medicus* of which so much has been said, is published in Detroit, and that the *Annals of Surgery* is published in St. Louis, and even the *Therapeutic Gazette*, although edited in "The City of Brotherly Love," is also published in Detroit? But these are *private business* enterprises and are run on *business* principles, yet they don't seek the National Capital to insure their success. How strange! How passing strange, that you should insist on THE JOURNAL of our Association to assume business risks which not a prosperous journal of the country will dare to assume.

Again, the Doctor says: "If a general and hearty consent to the removal of THE JOURNAL from Chicago to Washington should have been agreed to, then the *general business management* of the organ, and its *editorial work* will become *most important* subjects of consideration."

Why not tell the truth Doctor, although you should shame the Devil, and say that *already* the editorial and business management, (should THE JOURNAL be removed to Washington) has *been bargained for*, and instead of the horse pulling the cart, in this apparent scramble "for the loaves and fishes" the cart, poor thing, is trying to pull the horse. In fact it really thought at *one time* it had pulled the horse!

Just think of it, a "club building," in the National Capital with its *three* railroads, leading to "our father's

house" where we will *all* be at home! (when we get there), many of us, however, only once in from one to five years, but for which we are *all expected* to pay our hard earned money just the same; to accommodate the erudite editor *without practice or experience*, who with his friends and followers are to *occupy* "our fathers' mansion from day to day, and issue out editorial instructions from week to week to the practical hard working Doctors of our National Association. What a sublime idea! What a brilliant conception!

Nor is this all. The Doctor wants us to raise an extra \$10,000 to carry out this pet scheme of removing THE JOURNAL to Washington. Surely he has never suffered, or at least, is not suffering now from a severe attack of conservatism regarding any prospective financial embarrassment of the Association or its Journal. These facts alone are sufficient reasons for keeping THE JOURNAL at Chicago where it has grown from a *dependent child*, to a *strong, robust self-supporting man*; and which never has and does not now seek to incur the Association with any "Club Houses," or \$10,000 loans with which to entertain, and pay for an unpractical "supervising editor," who is expected to live in "our father's house" and fare sumptuously, every day, but who *must not practice* any for fear he loses some of his theoretical brain power, which must be kept in reserve to elevate the editorial standard of THE JOURNAL. Why, Doctor, don't you know that the very moment the American Medical Association decides to hold its annual meetings in any one city, I care not whether it be the "Queen City of the West"—Chicago, Washington, or San Francisco, just that moment the Association will commence to lose its membership, and will gradually succumb to the slow but fatal disease of inanition?

The sad fate of the National Board of Health should be a warning for us to steer clear of Washington with both the Association and its journal if we desire them to live out their natural expectancy of life. Are you not conscious of the fact that that august body was not only conceived, but born in the National Capital? Yet it soon came to an untimely end from a severe attack of federal marasmus. The political atmosphere of "our National Capital" soon withered this *once promising* offspring, which has long since passed the way of all the world. And yet, you would drag our now prosperous journal into these same death-dealing political fumes and hazard its chances for a long life and prosperity by so doing.

How unreasonable, how absurd it is to expect our National Journal to obtain a subscription list or an advertising patronage such as the *British Medical Journal* has now, in only seven years, when the latter journal has been thirty-seven years obtaining 15,000 members and subscribers, with an annual income of \$130,000, whilst we have only been *seven years* securing one-third the membership and one-fourth of the annual income. At this same rate the American Medical Association will only require *twenty-one years* to obtain a membership of 15,000, and less than *twenty-eight years*, the same annual income the *British Medical Journal* now has! or *sixteen years less* time than it required for the British Medical Association to obtain the same membership, and *nine years less* than it took the *British Medical Journal* to obtain the same annual income, and yet you have the audacity and gall to stand up before our Association and denounce the management of our Journal and condemn the place of its publication with all these cold facts staring you boldly in the face. Indeed, I am surprised and astounded at you, and the more I think of it the more maniacal it appears, until I am compelled to exclaim with Felix of old: Cornelius, "thou art surely beside thyself!"

R. HARVEY REED, M.D.

Mansfield, O., March 19, 1891.

MISCELLANY.

STATE MEDICAL SOCIETY MEETINGS IN 1891.—We give below a corrected list of State Medical Societies, with the name of the Secretary, and the place and date of meeting:

Ala. T. A. Means, Montgomery; Huntsville, April 14.
Ark. L. P. Gibson, Little Rock; Hot Springs, April 20.
Cal. W. W. Kerr, San Francisco; Sacramento, April 21.
Colo. H. W. McLaughlin, Denver; Denver, June 15.
Conn. N. E. Wordin, Bridgeport; Hartford, May 27.
Del. W. C. Pierce, Wilmington; Rehoboth, June 9.
Fla. J. D. Fernandez, Jacksonville; Pensacola, April 14.
Ga. King P. Moore, Macon, Augusta, April 15.
Ill. D. W. Graham, Chicago, Springfield, May 19.
Ind. E. S. Elder, Indianapolis; Indianapolis, June 10.
Iowa, C. E. Darnall, West Union; Waterloo, April 15.
Kan. W. S. Lindsay, Topeka; Wichita, May 12.
Ky. Steele Bailey, Stanford; Lexington, May 4.
La. P. B. McCutcheon, New Orleans; New Orleans, May 13.
Me. C. D. Smith, Portland; Portland, June 4.
Md. G. Lane Trenchard, Baltimore; Baltimore, April 25.
Mass. F. W. Goss, Boston; Boston, June 9.
Mich. C. W. Hitchcock, Detroit; Saginaw, June 11.
Minn. C. B. Witherle, St. Paul; Minneapolis, June 18.
Miss. W. E. Todd, Jackson; Meridian, April 15.
Mo. J. C. Mulhall, St. Louis; Excelsior Springs, May 12.
Mont. J. W. Gunn, Butte City; Helena, April 24.
Neb. M. L. Hildreth, Lyons; Lincoln, May 1.
N. H. G. P. Conn, Concord; Concord, June 15.
N. J. Wm. Pierson, Chattanooga; Nashville, June 23.
N. Y. E. D. Ferguson, Troy; New York, Oct. 25.
N. C. J. M. Hays, Oxford; Asheville, May 26.
Ohio, G. A. Collamore, Toledo; Put-in-Bay, June 17.
Ore. C. C. Strong, Portland.
Pa. Wm. B. Atkinson, Philadelphia; Reading, June 2.
R. I. W. R. White, Providence; Providence, June 11.
S. C. W. Peyre Porcher, Charleston; Anderson, June 9.
S. Dak. R. C. Warner, Mitchell; Chamberlain, June 10.
Tenn. D. E. Nelson, Chattanooga; Nashville, April 4.
Texas. F. E. Daniel, Austin; Waco, April 25.
Vt. D. C. Hawley, Burlington; Burlington, Oct. 15.
Va. L. B. Edwards, Richmond; Lynchburg, Oct. 27.
Wash. C. L. Flannigan, Olympia; Seattle, May 6.
W. Va. J. L. Fullerton, Charlestown; Fairmont, May 20.
Wis. J. R. McGill, Milwaukee; Madison, June 3.

POLICE SURVEILLANCE OF RAILROAD STREET CROSSINGS.—Anent the fact that in Chicago 105 persons were killed last year at railroad crossings of streets. *The Journal of the National Association of Railway Surgeons* editorially recommends police regulation of such crossings as the most important, i. e., such as have been found to be particularly hazardous from the activity of human traffic. Shut gates at railway crossings may prevent the passage of vehicles, but they do not stop many people from dodging around them and hurrying across the tracks in front of approaching trains.

STATE REGULATION OF PROFESSIONAL CONDUCT.—An Act has been passed and approved by the legislative authorities of Arkansas entitled: "An Act to Prevent Unprofessional Conduct in the Practice of Medicine." Sec. 9, of this Act reads as follows: "Unprofessional conduct for the purposes of this Act shall be held to be: First, The procuring, or aiding, or abetting in the procuring of criminal abortion. Second, Employing or using what are known as cappers, steerers or drummers, or the subsidizing of hotels or boarding-houses to procure practice. Third, The obtaining of any fee on the assurance that a manifestly incurable disease can be permanently cured. Fourth, The wilfully betraying a professional secret to the detriment of a patron. Fifth, All advertising of medical business in which untruthful and improbable statements are made. Sixth, All advertisement of any medicine or means whereby the monthly periods of women can be regulated or the menses reestablished. Seventh, Conviction of any offence involving moral turpitude. Eighth, Habitual drunkenness.

A COURSE IN HYGIENE.—A practical course in hygiene will be given this spring at Johns Hopkins University, under the charge of Dr. John S. Billings.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from March 14, 1891, to March 20, 1891.

Capt. William C. Shannon, Asst. Surgeon, now on duty at Ft. Apache, Ariz., will repair to this city and report in person to the Adjutant General of the Army for further orders. By direction of the Acting Secretary of War. Par. 5, S. O. 55, A. G. O., Washington, March 11, 1891.
Capt. Henry P. Birmingham, Asst. Surgeon, is granted leave of absence for one month, with permission to apply for an extension of one month, to take effect upon arrival at Boise Bks. of First Lieut. Robert R. Ball, Asst. Surgeon U. S. A. Par. 2, S. O. 59, Dept. of the Columbia, March 13, 1891.

Official List of Changes in the Medical Corps of the U. S. Navy, for the Week Ending March 21, 1891.

Medical Director C. J. Cleborne, detached from Naval Hospital, Norfolk, Va., and to Naval Hospital, Chelsea, Mass.
Medical Inspector T. N. Penrose, ordered in charge of Naval Hospital, Norfolk.
P. A. Surgeon John M. Steele, detached from Coast Survey Str. "Bache," and granted three months' leave of absence.
Surgeon James H. Gaines, placed on Retired List, March 15, 1891.
Surgeon M. L. Ruth, granted a month's leave from April 2 next, with permission to leave the United States.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine-Hospital Service, for the Two Weeks Ending March 21, 1891.

Surgeon H. H. Long, granted leave of absence for seven days, March 13, 1891.
Surgeon H. W. Austin, to proceed to Baltimore, Md., for special duty, March 14, 1891.
Surgeon John Goddard, detailed as chairman of Board for physical examination of officer of Revenue Marine Service, March 4, 1891.
P. A. Surgeon C. E. Banks, to proceed to Boston, Mass., on special duty, March 7, 1891.
Asst. Surgeon T. B. Perry, leave of absence extended thirty days, March 13, 1891.
Asst. Surgeon E. R. Houghton, detailed as recorder of Board for physical examination of officers of Revenue Marine Service, March 4, 1891.

ETIOLOGY AND TREATMENT OF
TYPHOID.

BY A. L. WAGNER, M.D.,
OF SOUTH BEND, IND.

Some of the matter contained in this discourse may seem irrelevant, but it was impossible, without some prelude, to make my meaning clear. It strikes me that physicians do not stop often enough to consider the significance and cause of symptoms in disease. Why does not one in sickness go on to recovery or to death without any such manifestation as a symptom? As compared to the time since the creation of man the short period that our profession has been able to render any service to mankind is but a day. These same symptoms were manifest in the systems of the preglacial man and long before they could be interpreted or associated as they now are. Are they then, as now so generally accepted, simply the signs of disease, the perverted and morbid conditions signaling to the physician to annihilate them and thus cure the disease which they, in the aggregate, are supposed to represent? Nature is, undoubtedly, always conservative. She will never kill one of her own creatures, and if disease attack the system of one of them she is up in arms at once to protect him. What are commonly called symptoms are Nature's remedies for the disease in which they are seen, or they are conditions, or collections of conditions following her remedies.

Now I wish to show that in a given disorder there are symptoms and sets of symptoms or signs, which are essentially different, and though speaking in the same tongue are dwelling upon a different topic. For example, and a more thorough study of disease, it seems rational to divide symptoms as follows:

1. Those symptoms that are due to or really are the morbid materials, *e. g.*, the hæmatozoa malaræ of Laveran, in ague, or the alkaloidal ptomaines in the diseases due to germs.

2. Those that are Nature's remedies and which are directed toward the destruction, removal or the modification of any foreign substance which

is incompatible with natural function. Nature's remedies are her only resources, and they differ to a great extent from those the physician can exhibit; but if the cause of the disease is to be removed and recovery to take place the physician must follow in Nature's lead or else leave her untrammelled in her efforts to relieve the sufferer. In typhoid fever this set of symptoms comprises elevation of temperature to burn out or oxidize the typhoid poison, and an antiseptic diarrhoea to prevent the growth of the *B. typhosus* and to remove the germs from the bowels. In tuberculosis these symptoms are fever for oxidation, expectoration to rid the economy of the poisoning material and profuse perspiration to wash out the oxidized products from the system.

3. The symptoms of this class might properly be called concomitant, as they occur as a sequel, not following in the wake of, but rather accompanying, the symptoms above. These represent the effect of Nature's remedies or the cardinal symptoms, and they are not directly curative. In phthisis we have wasting of tissue from the hectic fever, hæmorrhage from ulceration through the vessel wall in the lung. Here hæmorrhage and wasting are symptoms but they are not of any utility to the patient; they represent the effect of the remedy that Nature applies in the one instance, and the effect of the presence of the first class of symptoms, in the other. In typhoid this class is represented by the peculiar smell of the dejections, muscular debility, hæmorrhage, borborygmus, coated tongue, etc.

4. This class is due to the remedies the physician applies, and are very much more variable than those preceding, for the reason that the physician is more inconstant than Nature in prescribing. These symptoms are the physiological actions of the drugs administered. The first class given is no doubt not symptoms in reality but pathological indications, and represent the cause of disease.

Therefore, from the foregoing, a symptom is a *modified physiological function brought about for the better adaptation of the system to rid itself of a foreign and irritating substance.*

I here introduce this definition to accentuate the fact that what is commonly called a symptom is a modified physiological function, and that this

modification is brought about to meet the conditions arising from a morbid substance in the economy. If this is brought about to meet such condition, and it manifestly is, then we must accept the fact that what we speak of as symptoms are apparent (*i. e.*, easily seen) conditions or safeguards thrown out by the system, actuated by its "cell sense," to do battle against the foe.

My purpose in thus classifying symptoms is to show those symptoms that it is safe to combat; those that it is safe to augment, and those that it is safe and wise to ameliorate. In all cases we know that it is safe to remove or combat the cause. In typhoid the germ must be removed, and Nature is trying to do this by a diarrhoea of a peculiar kind. Then combat the cause by augmenting the remedy, diarrhoea. Look to it that this is not hampered by what I have denominated concomitant symptoms, tympanites, coated tongue, hæmorrhage, debility, etc., by correcting or assuaging them. My purpose in considering the fourth class as symptoms in any given disease, is for the better illustration of the preceding classes and to elucidate what I consider the true definition of a symptom.

For example, a lethal dose of morphia is administered; this is the disease. Deep sleep, insensibility, heart failure, failure of respiration, clammy skin, vomiting at the outset, great irritation of the skin (itching), especially of the nose and lips. These are concomitant symptoms. Now, this is a lethal dose, and strikes down with overwhelming force the centres and lines held in the hand of Nature as surely as a pistol ball would; but, notwithstanding, Nature reveals the line to be followed. The indications are but short lived, and are only to be noticed for a limited time after the dose is administered and are known collectively as the stage of stimulation, in which the temperature is elevated, arterial pressure increased, renal elimination hurried, respiration accelerated and, frequently, emesis. These are Nature's remedies, but they are not strong enough to ward off the trouble and the system sinks; but if a patient recover from a poisonous dose of morphia this sequence of symptoms must be prolonged.

In typhoid fever the germ *B. typhosus* is the cause; the alkaloid typhotoxine is the disease; fever, diarrhoea, anorexia and lassitude are the cardinal symptoms of Nature's remedies, and furred tongue, debility, tremors, etc., the concomitant symptoms, or the results of the *vis medicatrix nature*.

Etiology.—Geographical location, climate, season, age and diet are predisposing causes. It is with the last only that I wish to deal in conjunction with the direct exciting cause, the Koch-Eberth germ *B. typhosus*. After a case of typhoid in 1882 I began the investigation of the disease and its causes. This case was that of a Polish youth, and I did as many a more learned

physician has done before me, made a mistake in the diagnosis. Being fresh from college, and full of J. Milner Fothergill's "Indigestion and Biliousness," the trouble was pronounced subacute biliousness and was treated accordingly; but the fever continued, and though better, my patient did not recover as he should had it been a simple bilious attack. On the tenth day, in company with another physician, the diagnosis of typhoid was pronounced. From the fact that my patient had grown no worse the cholygogue treatment was continued, and on the sixteenth day we were pleased to see the temperature normal, and after this convalescence supervened rapidly. My next cases were treated on the same line and inquiry into the cause was instituted. It will be observed that the stools in enteric fever are dark greenish-brown, which I attribute to the presence of bile, and knowing that occlusion of the bile ducts permits a peculiar decomposition of the intestinal contents, I arrived at the conclusion that the presence of bile in the gut destroyed the typhoid germ in some manner, and consequently the absence of bile would favor the growth of the bacillus. Careful inquiry has been made in all my subsequent cases and symptoms of profound biliousness have been uniformly noted. If we but compare the symptoms of hepatic congestion and the prodromes of typhoid, we cannot but note their similarity. In both we have, in the language of Loomis, in his "Practical Medicine," "a grumbling headache, more or less aching of the limbs, a tired feeling all over, chilly sensations, flashes of heat and anorexia;" then we may have a slight diarrhoea, and always in the beginning a yellowish-white coat on the tongue. Listen for a moment to Murchison: "The symptoms of deficient excretion of bile are irregular bowels, colorless stools, loss of appetite, yellowish fur on the tongue, bitter taste in the mouth flatulence, languor, disinclination to exertion, great depression, frontal headache and heaviness." Fothergill adds: "I am so tired and sore all the time; as tired on awaking as retiring."

There is no doubt from the experiments of Charrin and Roger that bile is an antiseptic of no mean magnitude. They have shown that some of the components of bile are more energetic than others, especially were the tauro-cholates shown to be effective antiseptics. The bile salts as above were more powerful than bilirubin. Bufallin gives us the same results. Fothergill says, "the bile coloring matter and the bile acids go together, where the one is the other is not far away." Taurocholic acid ($C. H. NO S$) contains sulphur and is more profuse in the presence of bilirubin. When the fur on the tongue is most brown from the staining of its epithelium with the bilirubin, the taste is the most bitter from the presence of the taurocholate of soda. This shows that when the tongue is thus coated the liver is not acting and

that there is no bile being poured out into the intestine.

Desiring to ascertain whether bile has any antiseptic action on the typhoid germ I obtained a pure culture from one of my cases. From this I inoculated twelve halves of boiled potatoes. After twenty-four hours a few drops of carefully prepared ox bile were applied to the cultures. This was repeated for three days at intervals of six hours and the cultures made no further material progress, and on the seventh day were about as much developed as the untreated cultures were on the third day. Four others were treated with the bile after fifty-six hours, at which time the cultures had made considerable progress, and although the cultures continued to grow the growth was very slow, and on allowing the bile to drain off and dry, the germ growth did not continue. All the cultures emitted, in a very marked manner, the characteristic odor of the typhoid stool.

My second and third experiments were on six potatoes and six test tubes of nutrient gelatin on which were used fresh specimens of ox bile. These served to confirm the first experiments, but in a more positive manner. The cultures that were treated within the first twenty-four hours exhibited no growth whatever for many days.

The conclusions to be drawn from the above are: 1. Bile destroys or at least retards the growth of the *B. typhosus*, and apparently does so by retarding sporification; 2. It is reasonable to suppose that bile is excreted in larger quantities, coloring the stools and aiding peristalsis to rid the bowels of the germ; 3. If the above are true, then in the absence of bile in the bowel the germ would find no restriction to its growth and multiplication, and the diet that would produce biliousness would be a predisposing cause of typhoid; 4. If bile destroys the germ it must be one of Nature's remedies and should be encouraged to flow. It is generally stated that the most dangerous cases of typhoid are those in which the bowels refuse to act. In those cases where there is a profuse diarrhoea which is indicative of great irritation of the mucous lining of the bowel from the presence of the germs, the diarrhoea can be most easily checked, when in the early stage, and there is no reason to suspect much glandular necrosis, by a gentle cholagogue cathartic. Bile, then, is one of Nature's remedies.

The Cause and Use of Febrile Movements.—Before there can be a rise of temperature there must be a derangement of the thermotaxic function of the system. That is, the avenues for the escape of heat must be unstable and heat loss be less than heat production. Now if this alone constituted the phenomena of pyrexia the subject would be a simple one indeed, and all that would be required would be to aid radiation and conduction of the heat. But Wood and Reichert

have shown that the matter does not end here, for a high temperature may be present with a great amount of heat-loss going on, and by their calorimetric researches they have, with Donald Macalister, shown that the thermogenic function may be actively excited, and the sublingual temperature be little more than normal, or there may be little excitation of the thermogenic centre and a very high sublingual or rectal temperature, provided the conduction and radiation of heat be abolished or hindered. The significance of this is stated by Macalister *British Medical Journal*, Vol. 1, 1887, page 566, as follows: "The processes which issue in motion on the one hand and thermogenesis on the other are associated with chemical movements in the muscle, with metabolism, whose terminal steps are accretion of oxygen and excretion of carbonic acid and water. Both the contractile and the thermogenic stuffs are stored in the muscles but are not the same, but as far as function goes they are the muscle. Each can be exhausted, the thermogenic sometimes sooner than the contractile. Both are up-built by the circulating blood, but in some cases the contractile stuff sooner than the thermogenic. Both are affected by cold, but the thermogenic much sooner and more intensely than the contractile. We know but little of the chemistry of these metabolisms. Oxygen is taken up in each, and carbonic acid is eliminated, but the processes passed through between these terminal stages are more complex than simple oxidation. *This in health; but in the reconstructive part of the process is inadequate or absent, the balance of accounts a slight evidence of a nitrogenous residuum which is marked. The muscle substance will appear itself to be consumed; it will no longer be what I might call the circulating medium of consumption.* The cast-out muscle molecules are not excretory in the same sense that carbonic acid is excretory. *In fever the nitrogenized substance of the system have been consumed, and for some reason.*" Will we say that this substance has been consumed by the fever, or will we say that the fever has been fed by this combustible substance? Macalister again says *ibid.*: "Some of the figures show that as the course of the temperature varies, the rate of heat production may actually be highest when the temperature is lowest, an excessive rate of heat-loss overbear, and thus disguise a simultaneous excessive rate of heat production; and conversely, the time when the temperature is high may coincide with a time when the heat production is low."

If this tissue metabolism goes on regardless of the height of body temperature, then there is some other reason beside elimination, or rather the lack of elimination, for this heat being present. It is reasonably demonstrated by physiologists (Wood, Foster, Hale-White, Reichert), that there is a nervous centre which regulates the

production of heat in the animal body, which they call the thermotaxic centre. If this be excited, or rather stimulated, heat production is in excess; if it be depressed the usual thermogenesis does not occur. Now if this be true, is it, or is it not similar to the centre governing respiration, and when its function is most needed is it not called into the field of action there to do its duty? When the tissues need rebuilding they send out a dispatch over their telegraph lines to the central office, the brain, for food, and the central office again wires the commissariat, the stomach; and if there be no stores on hand it is here that the desire for food is felt. The tissues feel a need of oxygen. The message is flashed to the brain and thence onto its switch-board, from whence the message is conveyed to the respiratory centre which notifies the lungs to rapidly fill and empty themselves. Why do these dispatches have to be sent out? Because there is some obstruction to physiological function, and this substance must be something useless to the economy. Where there is a demand on the respiratory centre the offending material is carbonic acid gas. In the case of hunger the presence of the materials of retrograde metamorphosis is in excess of the building materials, or perhaps more accurately, there is felt the desire for more strength through more protoplasm, blood, chyle, food. If there is any offending material in the system which it is Nature's intent to burn out or oxidize, the alarm is sent to the centre governing the heat production. The thermogenic stuff is there in the system; and then comes the call for more oxygen. The conflagration goes on and the material is oxidized, and perhaps thus rendered wholly inert. What benefit then is to be derived from measures directed toward aiding evaporation, or radiation or conduction of the heat away from the body through the skin? It is true that some of the offending matter may be thus washed out of the system through the pores, or the immediately contiguous atom to the one being oxidized may be cooled off to await combustion on another day; but the material is there to be consumed and the tissue must be sacrificed to do it, for it matters not whether there be a high sublingual temperature or not, the consumption of the thermogenic and the contractile stuffs is progressing. It would be far more rational to prevent the irritating substance from entering the system, or where this is impossible from lack of accurate, scientific knowledge, to conserve the tissues, as we can do by furnishing something to the system easily oxidizable which would be burned in preference to the tissues.

By experimenting with bacteria it is ascertained that there are particular temperatures at which they thrive and grow, at which they cease to segregate and sporify, and at which they die.

The temperature at which they grow most luxuriantly is between 96°-99° F., that at which they cease to segregate and sporify is 111°-114° F. The most of them die outright at a temperature of 150° and the spore dies at 212°-220° F. You say then that the temperature has nothing to do with the germ in fevers, and only apparently makes it grow more rapidly. Granted that you may be right, but, let us inquire.

When the sublingual temperature is 98.6° F. the temperature in the hepatic vein is 103°-107° F., and if the sublingual rise to 105° we would have the hepatic temperature of 114° F. This of course will not kill the germ, but it is very effective in preventing multiplication by fission and sporification. Pasteur, Koch, Breger, Eberth and others tell us that the B. anthracis is not in the circulating blood but one or two hours before death ensues from its presence. Breger tells us the same thing also regarding the B. typhosus, when it is then also in the spleen. When the germus once enter the blood there is nothing to prevent their rapid multiplication except high temperature, which being interfered with, permits death to quickly ensue. Nature makes one final effort; the outlets for the escape of heat are closed, and an intense conflagration is lighted up in the body furnace, but it is then perhaps too late and the patient is said to have died of hyperpyrexia.

Again, the disease is not the germ but the ptomaine manufactured by the germ, and at certain temperatures it is rendered inert (Breger), or is formed into a less harmful product, which is perhaps excreted as a leucomaine, or else it is not formed at all. For instance, if in nutrient peptone broth cultures of B. typhosus remain at a temperature of 102.2° F. for twenty-four hours there will be no ptomaine, typhotoxine, formed, but in its stead there will appear creatine, a leucomaine of less harmful tendencies. Now how can we, in the face of the fact that the temperature of the liver is almost constantly 105° and the temperature requisite to convert typhotoxine into creatine is only 102.2°, say that pyrexia is not a remedy instead of a symptom, and that it ought to be interfered with? But hyperpyrexia? It will not occur if nature be aided in other quarters.

For two thousand years physicians have been engaged in a wild, hurried and anxious rage to discover some new remedy to combat fever. They have had tartar emetic, digitalis, aconite, veratrum, quinine, salicylic acid, antipyrin and acetanilid and still the fever goes on. We are told that the fever must be lowered or the patient will die. I do not believe that high temperature ever killed anyone. But we are told that the patient cannot live long with a temperature of 106° or 107° F. Of course they cannot; but this is no proof that they expire from hyperpyrexia.

When the fever suddenly flashes up to such dangerous height it indicates that the system's bulwarks have been overthrown, and that the germs are invading the blood and tissues generally, or more frequently it denotes a great influx of the alkaloids or the albumoses into the system, which immediately begins to burn them out, because they are there in large enough quantities to stimulate excessively the thermogenic centre. The larger the dose of typhotoxine injected under the skin the higher the temperature will run till a certain limit is reached, when the irritability of the thermogenic centre becomes exhausted and the temperature falls below the normal. If the above be true why do we ever give an antipyretic in typhoid that we have had under our care from the first? And above all, why is it ever necessary to give a cold bath? Cold bathing and a milk diet is the present treatment. Do we expect to depress the temperature below the growing point of the germs or the forming point of the ptomaine? The remedy is a good one in its place for it acts as a tonic to the system, and by contracting the surface arterioles it flushes the capillaries of the internal organs, and thus retards the absorption of the poison which is being manufactured in the bowels. It also possibly aids the elimination of the ptomaine already in the system. But all the previous methods of treating typhoid have required from four to six weeks for recovery. Now if a treatment that allows of a normal temperature in from ten to sixteen days be advanced, why still advocate an unnatural method of treatment that loses two or three weeks of the patient's time?

We do not now expect to cure ague with quinine by depressing the temperature, but by killing the hæmatozoa malarie of Laveran. Quinine is absorbed and circulates along side of the organism and destroys it by attacking its protoplasm. The B. typhosus is not in the blood till late in the disease, but exists by the million in the bowels and fecal matter. By actual experiment it has been demonstrated that bile kills or stunts them; shall ice baths and milk diet be ordered, or shall a cholagogue be exhibited?

Since mercurials are not cholagogues in reality, but serve to stimulate the liver and thus eliminate bile more rapidly than any other means at our command, it is preferable, since bile is in excess in the system and only needs to be eliminated, to begin with some mild preparation of mercury, such as calomel. This is administered for the first two or three doses in two- or three-grain powders, then the next six or eight doses in one-half or one-fourth grain doses, and then for six to ten days one-tenth of a grain at a dose every three or four hours. About the fifth or sixth day the salicylates, turpentine or salol which really cause a greater formation of bile, will be

of service in combination with the calomel, to the case. If the case is seen late and there is a very high temperature to combat, with great depression and wasting, conserve the tissues with alcohol. It is possible that the calomel may act directly as an antiseptic on the germs, but I have had quite the same results with the administration of podophyllin. Out of fifty-two cases that I have thus treated I have not observed one instance in which there appeared salivation. Of the fifty-two cases there were none that were not free from fever on the seventeenth day, and only one that ever had a temperature of 103.5° F., and he called me on the fifth day that he was confined to his bed.

Apropos of the action of bile on the intestinal contents and the utility of the cholagogue treatment set forth above, it might not be untimely here to say that the same comparative results obtain in treating summer diarrhoea of children in the same manner. Podophyllin, calomel, salol and turpentine continued, with an occasional dose of coto, have produced most brilliant results, and I apprehend that Dr. Boardman Reed's experience (*Practitioner*) in checking diarrhoea with podophyllin is a like result.

102 So. Michigan St.

SOME OF THE LESIONS INDUCED BY TYPHOID FEVER.

Read before the Cambridge Society for Medical Improvement, February 25, 1891.

BY AUGUSTUS P. CLARKE, A.M., M.D.,
OF CAMBRIDGE, MASS.

Perhaps no disease whose records have been embodied in medical literature is attended or followed by a greater variety of lesions than is that of typhoid fever. The functions of the great nerve centres, including the brain and spinal cord, as also those of the nervous system generally, are liable to be seriously influenced, weakened or interrupted, for periods of uncertain duration, by the occurrence of an attack of typhoid fever.

Among the sequels or complications that have been observed is dementia, insanity, loss of sight, aphasia, paraplegia and other forms of paralysis. Sometimes only one limb, as a leg or an arm; rarely, only an arm and a leg at the same time. At other times disturbances are limited to the functions of speech. Cases now and then occur, in which we have paralysis without appreciable anaesthesia. The more common forms are those in which both the motor and the sensory portions of the nerve are involved. Neuritis beginning at the peripheral portions of the nerve is not an uncommon sequel of typhoid fever. Another complication of typhoid fever is pneumonia. This is often of a limited extent, but occasionally it is more or less diffused. Perhaps the particular

position which the patient assumes during the first illness in the fever may have a controlling influence in the extent and severity toward that sequel of the disease. Formerly much was said in reference to pneumonia as a complication of disease. Such attacks of pneumonia were called "hydrostatic," from the supposed influence position of the patient exercised in favoring the gravitation of the blood and other fluids to the more dependent portions of the parenchyma of the lungs.

In my own practice I have met with three well marked cases of aphasia occurring in typhoid fever. The patients were young; their ages being 12, 14 and 17 years. The aphasia in each case occurred after the second week of the fever. The temperature had been unusually high, and much exhaustion had ensued. No paralysis, nor other morbid process of the nerves occurred. The patients at length fully recovered.

The record of the following case presents an affection of the eye: Mrs. B., aged 31 years and mother of three children, had the characteristic symptoms of typhoid fever, such as epistaxis, rose spots appearing on the seventh day following the initial chill. The patient had been very delirious, and had become much exhausted. After the fifth week she complained of pain in the eyes, more especially in the left one. Ophthalmoscopic examination revealed neuritis extending to both discs. After the temperature became normal she suffered from perversion of the senses, and at length became partially insane. There was no history of renal trouble, the urine at that time contained only traces of albumen. The patient finally recovered without sustaining permanent loss of vision.

Disease of the optic discs following typhoid fever is mentioned by Dr. Oglesby,¹ of Leeds. That author says that he has never met with a case without a distinct history of meningitis. "The majority of those patients," he says, "present objective symptoms indicative of acute kidney mischief, having a decided appearance of cellular dropsy of the face, with the usual pallor of such cases. It is very exceptional that albumen is found in the urine."

I have records of a case of severe laryngeal inflammation, following typhoid fever. The case occurred six years ago, in a man aged 42 years. The typhoid symptoms were quite characteristic. The morning decline, and the evening increase of temperature prevailed throughout the attack. From the onset there had been much delirium, also tympanites and a profuse diarrhoea. After the fourth week the patient showed decided improvement. On the fortieth day a dyspnoea ensued, though there was but little cough and no cardiac disturbance. For the next two weeks the symptoms were more se-

rious. The respiration became more and more difficult, and at length the patient appeared in imminent danger of suffocation. The late Dr. A. F. Holt saw with me for several times the case in consultation. It being evident that there was an abscess which was extending into the laryngeal perichondrium. On the sixty-first day operative measures were decided upon. By the use of cocaine we were enabled to reach the abscess without the necessity of resorting to laryngotomy. The patient ultimately recovered, though there remained a laryngeal stenosis. Two years later the patient died of acute pneumonia, hastened, no doubt, by the laryngeal constriction.

I have notes of four cases of pneumonia occurring as sequel or complication of typhoid fever. In one case in which the typhoid symptoms were well pronounced, pneumonia developed in the third week and led to a fatal termination. This occurred in a female aged 18 years. For some two years previous to the occurrence of her last sickness she had suffered from impaired health. In three cases the patients were aged respectively 17, 20 and 29 years. In two of the cases the area of dulness was limited. In the third case the whole of the right lung was involved. The patient did not recover until the fourth week after the onset of the pneumonic symptoms.

In a case of typhoid fever occurring in a woman aged 34 years, the mother of two children, acute pleurisy developed in the sixth week. There was marked dulness on percussion over the right side, also egophony and absence of vocal fremitus of that side except at the upper third. The effusion was moderate in amount. She recovered with slight retraction of the chest of that side. Two years later phthisis supervened, from which she died within eighteen months.

In one case of typhoid fever occurring in a man aged 41 years, facial erysipelas made its appearance on the forty-first day after the beginning of the febrile symptoms. This complication ran into the ninth week, causing an abscess of the scalp just back of the forehead.

Another complication I have met with is that of parotiditis. This occurred in the case of a man aged 37 years. The attack of typhoid in the patient was of a severe type. Inflammation of the right parotid began on the tenth day after the initial symptoms of the fever. Hope in the patient's recovery was entertained until the twenty-fourth day. Soon after that the patient rapidly sank, and died three days later. Suppuration of the parotid did not take place. The inflammation, however, extended into the cervical and axillary glands. This was the most marked case I have ever met with, in civil practice.

I recall cases occurring in the Spring and Summer of 1862, during the Peninsular campaign. At that time the occurrence of an affection of the parotid in a typhoid case was regarded as an ex-

¹ Boston Med. and Surg. Journal, Vol. cviii, p. 476.

tremely dangerous complication. Some forms of paralysis after typhoid fever have been reported by Dr. Ross.² Dr. Ross mentions two cases; in one case there was severe paraplegia attended with much pain, rigidity, and wasting of the limbs, but with no anesthesia. In the other the paralysis was unusually extensive, involving all the limbs, also the muscles of the palate. Both cases ended in recovery.

A case of paraplegia after typhoid fever occurring in my own practice was that of Mr. S., aged 29 years, a teacher in a Boston school. The fever had not been unusually severe, though the symptoms were well pronounced. After the fourth week the temperature became normal. The patient in other respects was also much improved, except that there was pain in the limbs and an inability to use them. The patient at first was unable to stand. Ten days later he was able to get about his room, with a sort of shuffling gait. Some weeks later he fully recovered and was able to resume the duties of his school.

Two cases affecting the muscles supplied by the circumflex nerve I have met with. One, a case of a child aged 6 years, occurred in my own practice. The other, a case of a man aged 21 years, occurred in the practice of the late Dr. Church. This case I saw in consultation. Each patient finally made a good recovery.

Two years ago I was called to attend a child aged 7 years, who had recently recovered from an attack of typhoid fever, and who was suffering from partial loss of speech. The palatal muscles were affected. The paresis resembled that supervening after diphtheria. The history of the symptoms clearly showed that her condition was the result of typhoid fever. She afterward greatly improved. I am now unable to state whether she ever fully recovered.

Two cases of periostitis occurring in typhoid fever have come under my treatment. The first patient, J. O., a girl aged 9 years. She suffered from typhoid fever upwards of three weeks. She was then able to be up and about her room. Six days later she was seized with a relapse which lasted nearly four weeks. The evening temperature was unusually high, there was much delirium. The patient refused all kinds of nourishment except milk and the stronger stimulants. The latter she took in abundance. After the fourth week of the relapse, her left elbow-joint became greatly inflamed and was much swollen. Suppuration of the elbow-joint ensued, necessitating a deep incision into the joint and a large amount of pus was evacuated. Several places in the periosteum of the ulna from elbow to wrist were the foci of suppuration; indeed, the whole shaft of the ulna was involved. The first abscess appeared in the periosteum near the left olecranon, and involved the elbow-joint. An abscess also

appeared on the opposite side of the joint. Both these abscesses communicated with each other. An inch below and more to the inside was a third abscess. On the same line and an inch below the first was a fourth abscess. Another formed midway between the other two. Another occurred in the middle third of the ulna. Another, the seventh, opened near the wrist, but fortunately did not involve the joint. From time to time several pieces of necrosed bone were discharged through the open sinuses formed by the suppurative processes. This patient finally recovered with a stiff elbow-joint. Dr. H. O. Marcy, and also Dr. Geo. H. Lyman, of Boston, saw the patient while she was suffering from the effects of the periosteal inflammation.

There was a peculiar interest attached to this case, as a suit by the parents was brought to recover compensation for the child's sickness and also for the loss of use of the arm. It appears that the mother, a short time immediately preceding the attack of the typhoid fever, was employed to do special work in a family in which there occurred a fatal case of typhoid fever. Without being informed of the dangers incident to such service, the mother returned to her own home, carrying from the sick-room a piece or pieces of bedding to be washed. Not long after this her own daughter, J. O., was seized with typhoid fever with results as above stated. Had the case not come to a settlement without a trial, some of the most important points relating to the responsibility of families to domestics would have been urged in the prosecution for judicial consideration.

The other case occurred in a lad, H. M., aged 13 years. The history of the case shows that he had studied hard at school; that often he had been out late at night to fulfil engagements as cornetist. When I was called, February 7, the patient showed the characteristic symptoms of typhoid fever. He had epistaxis, tympanites, headache, delirium; later rose spots, evening temperature higher than the morning. After the third week the typhoid symptoms abated; the patient was able to leave his bed. His recovery was soon interrupted by repeated chills, each chill being followed by a greatly increased temperature and an exacerbation of the other constitutional symptoms. In the right thigh, just above the knee, there was a most intense pain. Soon much swelling at that point developed. March 14, with Dr. H. O. Marcy's concurrence, I made a deep incision into the swelling and obtained a free discharge of pus. By liberal use of antiseptics and the drainage tube, the patient at length fully recovered without appreciable injury to the knee-joint.

On reviewing the history and symptoms of this case it might appear at first that the constitutional symptoms were wholly due to inflammation

² Braithwaite, part 97, p. 30.

of the periosteum, as there was a history of a fall upon the knee. The initial symptoms, however, from which the patient suffered were typical of typhoid fever; beside, after the third week there was for awhile an intermission, or rather cessation of the constitutional disturbance.

J. O. Affleck, M.D., reports three cases of periostitis in typhoid fever. These cases appeared in a total of 117 cases which were under treatment in 1884 (in the typhoid wards of the Fever Hospital of the Edinburgh Royal Infirmary). Two of them occurred in young men, aged each 21 years. One of them had periostitis commencing in the right tibia in the third week of the fever. This produced a recrudescence of the fever, and prolonged the case for four weeks, but the patient made a good recovery. The other showed symptoms of marked periostitis in the right humerus in the third week, and this was followed by a similar condition of the right tibia. Convalescence was slow, and after the periostitis had apparently departed, it reappeared in the right humerus, and an abscess formed. The patient ultimately recovered. The third case was that of a girl, aged 9 years. The attack reduced her to such a degree of exhaustion that, for a time, it seemed scarcely possible she could survive. In the fifth week, and just as the temperature had begun to subside, she was attacked with periostitis of the right humerus, which set up fever again and caused her intense suffering. Contrary to expectation, she recovered. No abscess formed, but the painful swelling of the shaft of the humerus continued for full six weeks from its appearance. Dr. Affleck refers to Sir James Paget's observations that periostitis with or without necrosis may be enumerated as one of the sequels of typhoid fever. Sir James had seen such cases when they occur only at advanced stages of convalescence, and when the patient was regarded as free from fever. Dr. Affleck says that periostitis may occur at the height of the fever, or when convalescence has no more than begun; that such a morbid condition may be regarded as a complication no less than as a sequel of typhoid fever.

Among a few of the more serious sequels which are liable to arise in typhoid fever is softening and degeneration of the tissues and organs belonging to the circulatory system. Cardiac thrombosis, emboli of the larger, and embolic occlusion of the smaller branches of that system, are not very uncommon occurrences of the typhoid state. Affections of the heart from such a cause were long since described by M. Louis, and also by earlier observers. Variation from the typical diurnal temperature is another peculiarity which is sometimes observed. Quite recently, in a case of typhoid fever occurring in a man aged 31 years,

there was a morning increase, and an evening decline in the temperature. The patient had been greatly exhausted from overwork, and from a diarrhoea which supervened at an early stage of the fever. The diarrhoea, however, was readily overcome. Delirium from the first stage was unusually marked. Though the patient was able to take a liberal amount of nourishment, including milk, broth and even stimulants, he had but a feeble and compressible pulse. He gradually lapsed into a cyanotic state, and died apparently of cardiac failure (if such a failure from such a cause ever occurs), in the fourth week of the fever.

In regard to the etiology of the sequels and complications of typhoid fever, it may be remarked that the typhoid bacilli and their ptomaines produce such changes in the tissues as to diminish their resisting power. The osseous tissues, as also the parenchyma of the lungs and of the other parts of the organism, being subjected to such influences, are thereby more easily invaded by the pyogenic and septic cocci. These invading elements, under such conditions, induce sooner or later, in one or more of the various tissues, an irritation, inflammation or suppuration. The severe and prolonged pyrexia also interferes with the nutrition of the nerves. This undoubtedly leads, occasionally, to dementia, insanity, and to cerebral affections generally; also to disturbances of nerves, sometimes at their origin, sometimes along their branches, and sometimes only at their periphery. The presence of such lesions and their extent will depend, no doubt, largely upon the susceptibility of the patient, the degree of exhaustion of the nutritive functions, and upon the nature, potency, and perhaps quantity of the invading cocci.

LECTURES.

EMPYEMA.

A Lecture delivered at the Post-Graduate Medical School, Chicago, January 21, 1897.

BY BAYARD HOLMES, M.D.,
OF CHICAGO, ILL.

No surgical procedure is so little studied and so often overlooked with such deplorable consequences as empyema.

One of my neighbors, who is quite deaf, recognized a case of right-sided empyema in a man 36 years old, and sent him immediately to one of our large hospitals. He remained in the hospital three weeks and was discharged to die of phthisis. My deaf neighbor was surprised that the true condition was not recognized, and fearing he had made a mistake, he drew out a syringe of pus with his hypodermic. Thus satisfied as to his own diagnostic acumen he took care of the patient and "promoted euthanasia."

Numerous instances have come to my knowledge when cases have not been recognized; others where, though recognized, proper and adequate treatment has not been instituted and others, though recognized and properly treated at first, the same degree of logic and skill has not been followed out in the subsequent treatment.

As an instance of the first kind I will mention a case which was observed in a man who was discharged from the Kankakee Insane Asylum to die from phthisis. This man recovered without any inhalations or injections in a remarkably short time, both of his insanity and of his phthisis, upon the evacuations and drainage of the right pleural cavity. Numbers of similar cases have come in the experience of almost every physician. Some of the cases even more mournful in their results.

My only excuse for calling attention to this disease is to enforce the teachings of modern mycological pathology in an instance which presents many peculiar difficulties and modifying elements.

There can certainly be no progressive suppuration without the presence of pyogenic bacteria. Every other form of inflammation (non-suppurative) in the pleural cavity is due to the infection of that cavity with non-pyogenic but *pathogenic bacteria* or other *microorganisms*. It follows from the anatomy of the pleura that except in penetrating wounds, its infection must always be secondary, and pleuritis and empyema must be looked upon as secondary and complicating diseases.

Pentzold observes that empyema is a frequent sequence of fibrinous pneumonia, and he looks upon it as a secondary infection of the pleura with pus microbes. The manner of this secondary infection I shall try to explain.

The normal physiological resistance of the peritoneum to infection is known from clinical experience and experiment to be very great. (Rinne.) This, as I have repeatedly asserted, is due to the evolution of a tolerance to infection from the great proximity of infective material in the intestinal canal. The same tolerance to infection has not been evolved in the pleural surfaces, for they are farther removed from sources of contamination.

The pleurae are most likely to be infected from the invasion of microorganisms from *infected air cells* or *bronchioles*. These small air spaces are almost as impervious to germs as the wad of cotton with which we stop our test-tubes.

Vinay describes a case of pneumo-thorax which originated in the rupture of the respiratory tract into a pleura upon the patient's rising from his bed. It healed without any inflammation or effusion and the temporary loss of function was removed in about two months. This case shows how perfectly the healthy lung filters the air

which passes through it. Similar results in pneumo-thorax are noticed when they result from stabs and gunshot wounds of the lung. So the pleurae are much less liable than the peritoneum to infection, and, therefore, natural selection has not guaranteed the same germicidal power in the pleural surfaces which we find in the peritoneum. For the same reason the pericardium being still farther removed from the possibility of infection, it is, therefore, still less tolerant when infected.

One of the causes which determines the localization of infection anywhere is an antecedent infection and coincident saturation of the germicidal power of the part and of the blood nourishing it.

Too little attention has been paid to the destructive power of the blood upon microorganisms. Allow me to recount in the briefest manner the experiments of Buchner and Netter, as well as those of Prudden. These investigators found that blood drawn from the living animal was able in two hours to destroy as many as 1,950 anthrax bacilli out of 5,000 mixed with each cubic centimeter of blood. It seems still stranger that the germicidal action was manifested in almost as great a degree in the defibrinated blood and in the serum alone. This germicidal action rapidly disappeared until after five hours the remaining germs began to multiply and the blood or blood serum then furnished the best possible culture material.

One of the causes, then, which undermines the localization of infection is an antecedent infection and a coincident saturation of, or exhaustion of this germicidal power of the blood. In the infection of the pleura with pus microbes, this is a prime essential. Suppurative disease rarely takes place in the pleura without a previous general septicæmia with some such parasite as the pneumo-coccus, the malarial plasmodium, the parasite of influenza, or one of the other infectious diseases. This coincident septicæmia and consequent saturation of the germicidal power of the blood, account for a *diminished physiological resistance*, always small in the pleura as we have already seen. It is *still* necessary to account for the presence of the pyogenic bacteria. Because this subject has not been adequately studied experimentally, it is possible only to conjecture the source of infection from analogous cases. In many cases of pleuritis, there is an extensive or limited pneumonia. In this pneumonic area, as time goes on, the bronchioles become infected to a greater or less depth, with the pyogenic bacteria which are always present in the air we breathe, and therefore in the larger bronchi. The oedema surrounding the bronchioles in the pneumonic area block the normal course of the lymphatics toward the hylus of the lung, and the current from active congestion turns in the direction of the periphery of the lung and the pleural cavity. For

a time the effused fluid is germ-free and is absorbed by the still healthy pleura over the unaffected portion of the lung and the parietes. In a series of experiments upon rabbits, undertaken by Fleiner, it is shown that fluids (blood and fluids holding coloring matter in suspension) injected into the pleural cavities are readily absorbed, and that the corpuscular elements or color granules are easily recognized in the mediastinal lymph glands. It seems that normal respiratory movements are necessary for this transfer of matter. This absorption, however, reaches a limit when the effused serum carries with it also so large a quantity of infectious germs that corresponding pathological changes take place in the absorbing pleura. Its epithelium becomes swollen, and multiplies imperfectly. Its normal physiological action is suspended; the whole pleural surface becomes the seat of suppuration. *A true empyema supervenes.* It is not to be supposed that under conditions of health the pleura is unable to resist a moderate amount of pyogenic infection for a moderately long time. When the lung and the whole circulation is suffering from malarial, pneumo-coccus, or other forms of infection, the first serum effused contains one of these pathogenic germs. This, many bacteriological experiments have demonstrated. The antecedent infection is responsible for the low vitality of the pleural surfaces and for the want of germicidal power in the effused serum itself.

From the investigations of Kracht it would appear that microorganisms are absent in simple serous effusions. Those found in purulent or fibrino-purulent pleuritis are not specific for the empyema, but point to a whole series of concomitant inflammations. Empyema only appears when the pleura is so injured or its cavity contains such a fluid that a suitable soil is present for the multiplication of pus cocci. Kracht experimented upon rabbits with a view of demonstrating the origin of empyema. He injected pus bacteria into the pleural cavity, and saw no injury result, but, when mixed with a large quantity of water or ptomaines pleuritis resulted.

In the same manner, tubercular effusions in the pleural cavities become infected from suppurative bronchitis with the pus microbes and a true empyema follows a tubercular effusion.

In these cases some of the most mournful errors have been made in the diagnosis. The physical signs and even the examination of the sputa have confirmed the diagnosis of tuberculosis. The patient has been pursuing a quiet and fairly satisfactory existence when, suddenly, chills, pain, fever and hectic appears. The examination of the chest does not discover more than increased consolidation but as time passes on, a considerable amount of pus may be discharged by the month, as a post-mortem examination may disclose a circumscribed empyema.

There are instances in which coagulation takes place in the effused serum, and larger or smaller clots resembling white thrombi fill the space between the pleurae. If the effusion takes place very rapidly, it may contain red blood corpuscles, and these again may be found in the clots. The cavity may be so filled with these fibrinous masses as to resemble a sponge. After the absorption of the serum, the solid portions of the effusion may be left behind and give rise to anomalous physical signs. When such a pleuritis becomes suppurative it is difficult to drain and it is wholly insusceptible to treatment by aspiration.

The indications for operating in cases of empyema depend very largely on the character of the infection. It may be stated in general terms that the serous pleuritic effusion is from the nature of the origin of effusions charged with the primary infective material; thus, in specific pneumonia, with the pneumo-coccus; in malaria, measles and influenza, with the organism which gives rise to the pneumonias of these diseases. These infective materials are incapable of producing suppuration under any circumstances, and their infective powers are limited in destructiveness and in time. Such serous effusions are ultimately completely absorbed without any loss of function in the parts concerned.

Suppurative empyema is due, as a rule, to the pyogenic staphylococci or streptococcus. A great number of investigators have found these alone or mixed with the infective parasite of the primary disease. It matters little which one of the pyogenic bacteria is the originator of the suppuration. It is in any case essentially progressive and destructive; there is only the remotest hope of the absorption of the pus. Two methods of termination have been observed. The pus has either been discharged through the thoracic walls or into the respiratory passages.

Beside the non-destructive pleuritic infection and suppurative pleuritis or true pyothorax, there remains one other important pathological and clinical manifestation of pleuritis, that is tubercular pleuritis.

Tubercular empyema may follow the perforation into the pleural cavity of a tubercular peripleuritic abscess going out from a tubercular osteitis in one of the ribs or vertebrae, or from a tubercular mediastinal lymph gland, and pyogenic empyema may arise from true pus cavities in the same localities.

Many authors have held that the presence of pleuritis without traumatism, is *primæ facie* evidence of tuberculosis, but this Dr. A. A. Smith¹ has shown from careful clinical observation followed in many cases by post-mortem examination, is not supported by the carefully considered facts. Pyæmic pleuritis occurs in the course of osteo myelitis, carbuncle and other suppurative

¹ Medical News, July 9, 1905.

diseases, and usually has the staphylococcus pyogenes aureus in the exudate. The streptococcus pyogenes is usually found in those cases which occur in puerperal sepsis or wound diseases. In tubercular pleuritis the tubercle bacillus is found only with difficulty. Tubercular pleuritis originates from infection of the pleura from neighboring tubercular organs, and principally from tubercular foci in the lungs. While it has been observed without other antecedent forms of pneumonia it is prone to follow non-tubercular and non-suppurative disease.

True or pyogenic empyema may arise from the puncture of the pleural cavity with an infected instrument. It was occasionally declared before the antiseptic period, and even well into it, that thoracentesis was followed, as a rule, by suppuration. This is denied by the methods and practice of modern operators. It does, however, occasionally occur. Gunshot wounds and stabs with sharp instruments without perforation of the lung and without pneumo-thorax is occasionally, if not as a rule, followed by suppurative pleuritis. That the perforation of the lung and consequent pneumo-thorax is not invariably followed by infection of the cavity is due to the germ-free condition of the air which has traversed for some distance through the moist bronchioles.

It must be remembered that in cases of pyæmia, pyothorax may arise and is to be accounted for in the same manner as in other forms of sepsis.

Marfan reduces the forms of empyema etiologically into three categories: 1. Those that follow pneumonia and are characterized by the presence of the pneumococcus in the exudate; 2. Those that occur in the course of pyæmia and contain the staphylococcus or the streptococcus; 3. Those that follow tuberculosis and contain the tubercle bacillus. The indications for operation, depending on the quantity of effusion, differ in respect to urgency the same in all kinds of empyema. Thus the effusion may be so great that it diminishes the lung capacity beyond the limit of existence. Life may thus be threatened in a one-sided effusion of such extent that it encroaches upon the cavity of the other lung, or when the opposite lung is already useless from pneumonia or other causes. In such cases the effusion must be immediately removed on account of its mechanical danger to life. The same may be said of such cases as are complicated by great interference with the circulation of the blood. Effusions, of even small extent, in both pleural cavities become dangerous, especially when complicated with pneumonia or bronchitis.

I will attempt here to demonstrate the action of a considerable effusion in one of the pleural cavities of a dog. In order that the circulatory complications may be at a minimum, I will use the right cavity. This I will fill by inserting this canula between the fourth and fifth rib and mid-

way between the sternum and spine. A considerable quantity of warm water flows into the cavity with great rapidity, and by raising the periculator a still larger quantity flows into the thorax, compressing the lung and pressing the mediastinum over the left side, diminishing the capacity of the left lung. This is manifest in the rapid breathing and the rapid and irregular pulse.

Such an interference with the function of the lung calls for immediate evacuation of the fluid without regard to the nature of the fluid or the character of the coincident inflammation.

There is another less urgent, but not less positive, indication for operation in those cases of effusion which are infected with pyogenic bacteria. It matters not what the original effusion may have been, or what the condition of the patient may be in other respects, the presence of a suppurative disease in the pleural cavity, or in both of them, is a positive indication for immediate and permanent removal. The suppurative disease is progressive and destructive, and never terminates favorably except in drainage and cicatrization of the suppurating surfaces, and closure of the cavity. The temporary or interrupted drainage of the pleura is not adequate in such cases, and cannot meet the positive indication.

The treatment of tubercular effusions into the pleural cavity may be stated in almost as positive terms. It is assumed that the tubercular infection is unmixed with suppurative disease. The focus of tubercular disease is assumed to be in the lung and beyond the power of the operator to remove. The effusion is not usually large, and is apt to be circumscribed by adhesions. The wall of the cavity is covered by tubercular granulation tissue and is sometimes found little more than a tortuous tubercular channel. Drainage by free incision is followed sooner or later (and in spite of the most careful antiseptic treatment), by pyogenic infection of the tubercular tract, and, when the opening begins to close, by symptoms of sepsis. Neither simple incision and antiseptic irrigation nor the excision of a portion of a rib and *evident* of the cavity is followed by a speedy recovery. The tubercular disease in the other part of the thorax is apt to speedily carry off the patient. It may be said that there is no positive contra-indication to operation on tubercular empyemas, and that they may be operated on when there is any special indication. This special indication may be found in the size of the cavity, in the accessibility of the original focus, or in the otherwise healthy condition of the patient. That the drainage of tubercular pleuras should not be undertaken with any favorable prognosis, except in the young, and when these follow tubercular disease in an accessible bone or other part and is not accompanied by an extensive disease in other parts of the thorax, passes without saying.

In removing pleuritic effusions a great obstacle is met in the contractility of the lung and its tendency to immediately collapse and retract to the upper and posterior part of the thorax under the pressure of the atmosphere. This is a difficulty nowhere else met with, and one which has long been looked upon as sufficient to interdict the opening of the pleural cavity under any circumstance. This is termed the elasticity of the lung, and it has been estimated by Hutchinson to be equal to one-half pound to the square inch. The pleural cavity may be opened into a partial vacuum and the collapse thus avoided, or the function of a single lung may be dispensed with. Thus we have two principal methods of draining the pleura—the one into a vacuum, and the other against a full atmospheric pressure.

I shall attempt to show you with the animal before us just how great is the contractile power of the lung of the living dog. Taking the percolator down and placing it some inches below the canula, the fluid flows rapidly from the thorax into the percolator as is indicated by the height of the water in that vessel and by the greater ease in respiration which the dog manifests. Fourteen inches is $\frac{1}{4}$ of 348 inches or $\frac{1}{24}$ of an atmosphere, which corresponds very well with the estimation of Hutchinson for the human lung.

Of all the methods of removing a pleuritic liquid effusion, that originally proposed by Staniski is the simplest and attended with the fewest dangers. This is the aspiration with a small trocar which has come so much in vogue since the perfection of the apparatus. For effusions which are infected with microorganisms of a non-destructive character, and for those effusions which are removed solely on account of their extent, it is the most serviceable and desirable method. It is not to be used in cases of pyogenic infection with the hope of effecting an arrest of the destructive disease. However, when so modified as to be used continuously it may be of the greatest advantage to those adults who can have the necessary attention from skilled nurses or physicians, and when it is instituted early enough to preserve the elasticity of the lung. When advantage is taken of the weight of a column of antiseptic solution for the aspirator this becomes the recently much lauded method of Brelau. Whether it can be depended upon for the complete removal of the products of suppurative pleuritis, experience has not yet adequately demonstrated. It seems to promise the most favorable results when instituted early and so vigorously as to remove nearly all the effusion, and, at the same time, bring the granulating pulmonary and parietal pleural surfaces together and secure a rapid obliteration of the cavity. It would accomplish enough if it would do this and limit the effusion to a small cavity, which could be afterwards drained by incision. It is the only method

which can be used in bilateral pleurisies of great extent. It commends itself to the patient as a less formidable operation than incision or rib-resection, and would, therefore, be likely to be undertaken early. With a proper apparatus to be made from any exploring aspirator and a long rubber tube, it is within the reach of every physician, and the difficulties and dangers of thoracotomy with constant aspiration are not great. The feeding of the siphon with an antiseptic solution on the principle of a Sprengel pump, as here proposed, may be found to be a safeguard in filling the tube which might become clogged or full of gases.

The following method is employed by Fürbinger in such cases of pleuritic exudations as are of long standing, and with little pressure. He takes advantage of the sucking power of the mouth to remove the fluid. A glass tube entering the bottom of an irrigator bottle is connected with the trocar by means of a rubber tube. Another tube from the top of the bottle is used as an exhausting tube.

I will try to evacuate the air which has purposely been allowed to enter this dog's pleura. The percolator is hung up three or four feet above the dog's body. An aspirator needle having a calibre of about a millimetre is now put on the end of the delivery tube. This needle is thrust into the rubber tube which connects the canula in the thorax with the basin below, and it is pointed downwards. As soon as the fluid is allowed to flow from the percolator it fills the waste tube, and the weight of this column of water aspirates the air from the thorax and may be seen escaping in bubbles from the end of the tube. Percussion over the lung now demonstrates the absence of air in the thorax and the presence of the expanded lung. The only remaining method of treatment consists in free incision and drainage. This is accomplished in a number of ways.

An incision is made in the axillary line and at the upper border of a rib into the centre of the effusion. The finger is passed into the incision and any information gained which the palpation affords. A rubber or other drainage tube is passed on the finger or forceps into the cavity and placed in the most advantageous position for drainage. The cavity may or may not now be washed out with a warm antiseptic solution and carefully dressed. This antiseptic irrigation and dressing are to be repeated every day with the most conscientious care and scrupulous antiseptic precautions. At the end of a week or two the discharge of pus will be found to have disappeared. Then if the method of Professor Quine and Bouvert is to be followed a still more careful antiseptic irrigation is to be employed, and the tube removed entirely, and the hole in the side stopped with a stick of iodoform. The dressing is left on for

two weeks or more, and the air and other contents of the cavity left to be absorbed by the now clean and healthy pleura. There is no reason why this should not fill all the indications of any operation, viz.: First, to evacuate the pus. Second, to prevent the production of more purulent matter, and third, to restore the respiratory apparatus to its normal condition. I must admit that while there is no reason to think that the pleural cavity may not thus be sterilized, our experience has been so unfortunate that until Professor Quine reported his cases it had not been regularly practiced.

At the German Congress for Internal Medicine referred to, Mosler alone advocated simple incision and drainage. The treatment most favorably received there was Buelau's method and the subperiosteal excision of a rib and drainage without antiseptic irrigation.

As to the site of operation, it must be admitted that a great many mistakes have been made both by writers and operators, and Godlee alone has put the matter exactly. The retraction of the diaphragm is more rapid than the retraction of the lung, and the opening into the thorax should be at least as high as the centre of the effusion in all cases in which drainage is made against the atmosphere. In case drainage is made into a vacuum after the manner of Buelau, the locality of the fissure between the lobes of the lung presents some obvious advantages. Dr. Marshall's muscle-free spot is certainly too far forward. The drainage can be better accomplished in the axillary line notwithstanding the amount of muscle and fascia.

The second method of drainage against the full atmospheric pressure is incision, counter-incision and through and through drainage. This method certainly secures better drainage and gives an opportunity for irrigation without danger of distending the cavity and interfering with the retraction of the lung. It hardly offers the best means of restoring the respiratory organs to their normal condition. It is the method which would be least likely to be received by the patient, and it has few advocates except in England.

The subperiosteal excision of a large portion of a rib and the drainage of the cavity by one or more tubes through the defect thus established. This is the method to be used in all cases which cannot have the care of a skilled nurse and the care of a careful and scrupulous physician. The drainage is established in the most comprehensive manner and is accompanied by the fewest dangers. It is the method best adapted to those cases that must take care of themselves.

Through and through drainage and insufflation of dry air. This method offers the same advantages as perrigation, with the advantage of scab formation and destruction of the infection by desiccation.

The perfusion of air has also (1866) been practiced by Roser, and later, combined with antiseptic liquid irrigation, by Quincke, and by Ewart and Fitzroy.

When pyogenic and non tubercular empyemas are treated by any one of the preceding methods early in their formation, there is the greatest hope of a restoration of the functions of the respiratory apparatus to its integrity. When treatment is inadequate to meet the indications, or when it is delayed, such serious changes take place in the thorax that new indications arise. Thus spontaneous discharge of the pus may take place through the bronchi, and the cavity formerly filled with pus will come to be occupied with pus and air. If the cavity is small, or favorably situated, it may drain sufficiently into the bronchus to close, and recovery will be nearly perfect. Again, if drainage is not instituted early in the course of the disease, the lung will be pressed back and up and adhesions will be formed between the walls of the thorax, and the collapsed and shrunken lung, which will prevent its ever being able to fill the pleural cavity again. This compression, with coincident infection, may result in gangrene of the lung and in the invasion of the empyemic fluid and the dead tissues by saprophytic bacteria and other organisms, and the production of a complicating sepsis of a grave nature. This invasion takes place from the bronchial tubes, which are always filled with saprophytic bacteria and other putrefactive organisms.

When such adhesions or such destruction has taken place before the case comes to treatment, or when the methods instituted have been inadequate to close the cavity entirely, it may be necessary to depress the thoracic wall so that it will come in contact with the surface of the collapsed lung. This is done by the excision of a sufficient number and extent of ribs to meet the indication. (Estlander.)

This review of the etiology of pyothorax makes it possible to formulate the following positive indications for operation:

1. Serious effusions must be removed whenever they interfere with respiration or circulation by their extent, or when they show a tendency to remain after recovery from the primary disease which gave rise to their presence. The aspirator may be found sufficient in these cases, but when inadequate after repeated trials, one of the more radical and permanent methods of drainage must be resorted to.

2. Pyogenic and tubercular effusions of large size or of small size must be immediately and permanently drained.

3. Drainage into a vacuum must be practiced in all cases of bilateral effusion without adhesive limitation, and in those cases of unilateral effusion in which the opposite lung is so incapacitated as to be inadequate for respiration. It may be

practiced in all cases in which the expansibility of the lung is intact and the patient can have skilled attention. It will be found of the greatest value in limiting the extent of the empyemic cavity, which may be afterward drained against the atmosphere.

4. Intercostal incision and antiseptic irrigation of the cavity to a point reaching a practically aseptic condition of the same, and permanent closure of the incision, is indicated when the expansibility of the lung is intact and the skill of the operator is sufficient.

5. Rib resection and thorough drainage should be practiced in all cases of tubercular effusion, and pyogenic effusions which are not treated early, or those occurring in patients who cannot have the best of care.

6. Operation must never be delayed on account of the extreme condition of the patient, nor on account of the presence of tuberculosis in one or both lungs, nor on account of the presence of pneumonia on the same side. All of these conditions are additional indications for radical operation.

PROPOSED MEDICAL LEGISLATION.

BY HENRY A. RILEY, ESQ.,
OF NEW YORK.

The Legislatures of many of the States are now in session, and in most of them measures have been proposed, of more or less importance, affecting medical practice or public health. It is difficult to present a full statement of all these bills, but the substance of many of them has been published in the daily papers and will be of interest.

In New York the principal bills are the following: One removing the pauper insane from the county poorhouses and transferring them to the State Asylums. This involves the expenditure of about \$500,000 for a new building to accommodate the new patients, and has been actively opposed by local officials who have found some pecuniary or other advantage in keeping the insane in the poorhouses, which are badly adapted for the care of such patients. The general sentiment of the profession and of humane persons is strongly in favor of the bill, and it has within the last few days received the Governor's signature and become a law. Another measure of great, though local, importance requires the appointment of matrons at the police stations in New York City, to care for women who may be arrested or apply for shelter. This bill, appealing as it does to the sentiments of humanity and decency, has also just become a law. Another measure of general importance provides for a Park in the Adirondacks for the purpose of preserving the forests from destruction, and conserving the water supply at the sources of the Hud-

son. The plans proposed involve the expenditure of not far from \$3,000,000, and while the Legislature will not appropriate so large a sum, it is probable that a beginning will be made, and the State committed to the sound policy of preserving its forest area.

In Connecticut a bill has been prepared to regulate the practice of medicine, and this provides for education at reputable institutions and the possession of diplomas by all practitioners residing in the State. Examinations by medical boards will also be required.

In Pennsylvania there are two measures providing for the regulation of medical practice—one emanating from the Allopathic school and one from the Homœopathic. The first provides for a Board of Examiners consisting of nine members, who shall have been in active practice for not less than ten years. The term of office is for three years. Not more than one shall be appointed from the same county, and none shall be a member of the faculty or staff of any medical school or college. The applicants shall be examined in anatomy, physiology, chemistry, toxicology, pathology, hygiene, materia medica and therapeutics, principles of medicine, surgery and obstetrics. Any candidate for examination may choose the system of materia medica and therapeutics in which he or she shall be examined, and no one shall be rejected on account of adherence to any school of practice. The bill proposed by the Homœopathic Medical Society is similar in some points, but quite different in others. The Board of Examiners is to consist of nine members, who must have been in practice for five years, and the term of office is six years. The Board shall have power to fix the grade of preliminary education required of all students entering a medical college, and shall also establish the minimum curriculum in medical schools, and the length of the course of studies requisite to graduation. The course of instruction shall not be less than four years. The Board shall inquire into the fitness to practice of graduates of any college having a lower standard than that required by the Board of State institutions. The main point of difference in the two bills is that the one proposed by the Allopathic school vests the appointment of the members of the Board in the Governor without prescribing the school to which they shall belong, and one of the State medical journals says that the different schools ought to be represented according to their relative numbers in the State. The bill of the Homœopathic school requires the Governor to appoint equally from lists presented to him by the Allopathic, Homœopathic and Eclectic Societies of the State.

In Michigan no special legislation regarding medical practice is reported, but it is said that the Governor advises the abolition of the State Board of Health and that the Legislature may adopt the

suggestion. This would certainly be a retrograde step, and would no doubt be a cause for subsequent regret.

In Maine the State Health Board has introduced a bill providing for the registration of vital statistics. It is rather strange that so important a matter as this should not have been already under legal sanction. The official record of births, marriages and deaths, arranged in such a manner as to be thoroughly reliable and readily accessible, is held by most civilized communities to be a prime necessity, and no doubt the lack of such a record has caused already great inconvenience in Maine.

In Missouri there is a bill requiring all medical colleges in the State to adopt three courses of lectures as a condition for graduation. Most of the colleges are said to favor the measure, and certainly the requirement is small enough if other States are considering the matter of requiring four years of study, before granting a diploma. Another measure pending in the Missouri Legislature touches on the regulation of prostitution. The provisions are modeled after the German laws on the subject.

In Illinois the State Board of Health, by virtue of legislation already enacted, has decided that it will not recognize a foreign diploma which does not confer upon its holder the right to practice medicine in the country in which it was granted. The holder of an Austrian, a German, Russian or Swiss diploma wishing to practice in Illinois, must hereafter pass an examination before the Board, unless he have a pass certificate from a Government examining commission. The holder of a Canadian diploma, unless a licentiate of the College of Physicians and Surgeons of Ontario and Quebec, must pass an examination in order to be licensed in Illinois.

In Oregon a bill has been introduced regulating medical practice, and part of it touches on medical ethics, and provides for the revocation of licenses in case of unprofessional conduct. The acts which will cause a revocation are as follows: *First*, the procuring, or aiding and abetting in procuring a criminal abortion. *Second*, The employing of what are known as cappers or steerers. *Third*, the obtaining of any fee on the assurance that a manifestly incurable disease can be permanently cured. *Fourth*, the wilful betraying of a professional secret. *Fifth*, all advertising of medical business in which untruthful and improbable statements are made. *Sixth*, all advertising of any medicine or of any means whereby the monthly periods of women can be regulated, or the menses reestablished if suppressed. *Seventh*, conviction of any offense involving moral turpitude. *Eighth*, habitual intemperance.

In California there is a proposed measure for regulating the practice of medicine. It establishes a State Board of Medical Examiners, con-

sisting of seven members, who are to be appointed by the Governor. One member is to be appointed from each of the well-established medical schools, and the others are at large.

Probably a number of other States are contemplating legislation somewhat along the lines of the bills mentioned above, but no statement of such legislation has been noticed in the public journals.

A statement will be made in these columns, after the adjournment of the Legislatures, of the measures which actually became laws.

MEDICAL PROGRESS.

Therapeutics and Pharmacology.

TREATMENT OF ICTERUS WITH TURPENTINE.—CARREAU (*La Semaine Médicale*, March 11, 1891) recommends the use of large doses of ozonized turpentine in the treatment of grave forms of jaundice. It is administered in the form of capsules, as many as sixty being given in the first thirty-six hours. In case of obstinate vomiting in which the stomach rejects the capsules, the drug may be administered hypodermically, the following mixture being employed: Essence of ozonized turpentine (*Codex Française*) 10 grams, liquid vaseline 50 grams. In one case of grave icterus, attended with fever, the writer employed twenty-three injections in thirty-six hours. The symptoms rapidly improved, and at the end of a few days the patient was convalescent.

TREATMENT OF ERYSIPELAS WITH GLYCEROLE OF SALICYLATE OF SODIUM.—DR. S. C. INGLESSIS (*La Semaine Médicale*, March 4, 1891) has employed a solution of salicylate of sodium, in glycerine, in the treatment of erysipelas. The solution should have a strength of from 4 to 6 per centum and be used each four or six hours, the affected part being protected with a layer of cotton. At the same time, in the absence of heart weakness, or albuminuria, salicylate of sodium is given internally, about two grams in each twenty-four hours.

The writer has treated thirty-six cases by this method, and notes favorable results. The application immediately lessens the pain and discharge, and shortens the disease.

Medicine.

ADDITIONAL OBSERVATIONS UPON CANTHARIDIN.—At the meeting of the Berlin Medical Society, held March 4 (*La Semaine Médicale*), SAALFELD presented a patient suffering from lupus who had been treated by injections of the alkaline solution of cantharidin. The ulcerating lupus had become flat, pale, and was apparently disappearing. The Landgraf had injected the

solution in a series of cases affected with acute laryngeal troubles, but had not noted any results. In nine patients with chronic trouble he had come to the following conclusions: That the remedy caused an œdema of the mucous membrane, expectoration was facilitated, the redness of the vocal cords diminished. He absolutely ignored the question of the remedy producing a cure. Lublinski had observed after the injections pain and strangury, but neither albuminuria nor hæmaturia. Expectoration was facilitated and ulcerations contracted and healed. A patient affected with laryngeal and pulmonary phthisis, and presenting a lupus on the back of the hand, was markedly relieved by the injections. Fränkel had not observed a case of perfect recovery from the injections. Since his last communication he had seen several cases of albuminuria, so that he now examined the urine after each injection.

Surgery.

SURGICAL TREATMENT OF PULMONARY CAVITIES.—The bold endeavor to radically attack phthisical cavities and drain them, although introduced some years ago, has been lately receiving fresh advocacy, especially in relation to the treatment of phthisis by Koch's "tuberculin." Many of the dangers of this remedy in advanced cases of phthisis rest upon the retention of necrotic material within the lung, and the liability to its being inhaled into previously unaffected areas. Dr. Sonnenberg recently operated upon four cases undergoing this treatment, and Dr. E. Leser of Halle reports two more. One of these was a female aged 43, who had had symptoms for four years, and presented physical signs of excavation at the left apex. The operation consisted in making an incision in the first intercostal space, 7 centimetres long, and, after dividing the muscles and securing blood-vessels, introducing a trocar in the direction of the cavity. Although no fluid could be obtained, it was evident that the point of the trocar was in the cavity, and the pleura being firmly adherent, an aperture was bored through the layer of tissue overlying the cavity by means of a Paquelin's cautery, the trocar being taken as a guide. The cavity was the size of an apple, had somewhat irregular walls, and was coated with flakes of inspissated pus and caseous matter; these were removed, and the cavity stuffed with antiseptic gauze. Subsequently the patient was injected with Koch's "tuberculin," which always caused increased discharge from the cavity; and later still some of the fluid was directly introduced into the cavity itself. At the last report the patient had improved much in general health, and the cavity had dwindled to one-half its former size. The second case, a man aged 42, was similar, except that in him the cavity was no larger than a chestnut, and was situated at the right apex. Here, too, the use of tu-

berculin produced increased discharge, and on one occasion its injection into the cavity was followed by severe vomiting, dyspnoea, and other alarming symptoms. Dr. Leser, however, thinks this mode of treatment has a future before it. At present he would make it a *sine quâ non* that the costal and pulmonary pleurae should be firmly united, as they usually are when cavities are of some standing, and he enters fully into the technique of the operation, laying stress upon having a fairly large incision through the thoracic wall, but not a very large aperture made in the lung, since this will be sure to increase by sloughing. The notable feature of these cases seems to be the immediate relief to cough and expectoration given by the external opening, although, when the injections are resorted to, the secretion becomes so much more abundant.—*The Lancet*.

EXPERIMENTS TO DETERMINE THE CENTRE OF RESPIRATION.—DR. LABORDE communicates to the Comptes Rendus de la Société de Biologie the results of experiments made by him to ascertain the nerve centre for respiration, promising a larger work at some future time. He found that superficial mechanical injury to the region of the *alae cineræ* does not accelerate respiration; a deep puncture decreases, or even temporarily arrests, respiration; if the injury penetrates at least to the middle of the substance, respiration may cease altogether. This result is always obtained if a certain circumscribed portion of the substance is canterized with the hot iron. This portion need in the rabbit be only half a millimetre in diameter, in the dog from one to two millimetres. The iron must, however, enter immediately above the apex calami, and must penetrate at least half the substance from the raphe. If the injury is unilateral, respiration may continue for some little time on the opposite side. Total separation of the medulla below the apex calami always arrests respiration of the trunk, while that of the head continues for some time. Spinal reflexes continue, and even increase; irregular superficial contractions of the respiratory muscles, leading to no results, may be observed. The increase of the reflex action is especially remarkable in newborn animals. No parts of the brain above the medulla oblongata, including the cortex, the corpora quadrigemina, and thalamus optici, have any specific influence whatever on the respiratory muscles.—*The Lancet*.

Bacteriology.

ETIOLOGY OF GROUSE DISEASE.—PROFESSOR E. KLEIN (*Cent. f. Bak. Parasitenk.*) finds that the bacillus of the grouse disease as it occurs in autumn is not nearly so virulent as that obtained from the disease during the spring months, the bacilli being obtained from the heart blood in the autumn and from the lungs in the spring.

SATURDAY, APRIL 4, 1891.

KOCH'S TUBERCULIN IN PULMONARY TUBERCULOSIS.

As we continue to receive letters from physicians in different parts of the country anxiously inquiring how and where they can obtain Koch's Lymph or *Tuberculin* with which to treat some of their consumptive patients, we think it proper to call the attention of all general practitioners to the present status of the Koch treatment, particularly in relation to pulmonary tuberculosis. And we would remind all inquirers that we know of no mode of obtaining a supply of the *Tuberculin*, except by application to Koch's laboratory in Berlin, Prussia. There is none in the drug market of this or any other country, and no one outside of Koch's laboratory knows how it is made, or precisely what its active ingredients are. The authorities at Berlin simply authorized the remedy to be furnished in limited quantities to be used in hospitals where the patients could be kept under constant observation, and reliable record made of the results. Under this regulation it has been obtained and used with the utmost care in many of the hospitals in the different countries of Europe, and in the chief cities of this country during the last three or four months. The results have been faithfully reported from week to week in the leading medical journals of this and other countries.

It has been used chiefly in cases of lupus and tuberculous affections of the external lymphatic glands, bones and joints, and in a large number of cases of pulmonary tuberculosis. It has also been used in a limited number of cases of cancer

and lepra, but generally with negative results. A careful review of all these reports seems to justify the following summary of results at this stage of the investigation:

First, The remedy when used in the manner and in the doses advised by Dr. Koch, has in most instances affected the human system in the manner claimed by him; although the febrile reactions have varied very much in different cases and sometimes at different times in the same patient, both in regard to intensity and duration. The effect of the remedy on tubercular tissue has also been abundantly demonstrated, especially in lupus and such tubercular cases as admitted of free external drainage; while the numerous post-mortem examinations by VIRCHOW and others show, not only the same necrotic effect upon the tubercular tissue of the lungs and other internal tissues, but also the rapid diffusion of the bacilli in the blood and tissues previously unaffected.

Second, In perhaps two-thirds of the cases of lupus and such tuberculous joints and glands as have free external openings, the injections of *Tuberculin* have been followed by marked improvement and in from three to six weeks some of them have appeared nearly well, while in many cases tolerance to the remedy was soon acquired and improvement ceased. In the remaining third of this class of cases no improvement was obtained and some of them were made worse. One girl, 17 years of age, with lupus of the face, received a single injection of two milligrams, which was followed by violent febrile reaction and death in about thirty-six hours.

In some of the early cases that were reported as nearly or quite well, the disease has since returned with as much activity as before, thus showing that even in the most favorable cases the curative effects of the remedy may prove only temporary.

Third, The number of cases of pulmonary tuberculosis that have now been treated with *Tuberculin* aggregates many hundreds. A large majority of them have been described as in the early stage of the disease, *i. e.*, before the softening or disintegration of tubercular masses, or the formation of cavities in the lungs. A much smaller number presented the physical signs of some suppurative or small cavities; while a still smaller number were plainly in the advanced

stage of the disease. In the two groups of cases last mentioned, the *Tuberculin* treatment has pretty uniformly accelerated the progress towards a fatal result.

In the first group named, supposed to contain only cases in the early stage of pulmonary tubercular disease, the first effect of the *Tuberculin* injections has pretty uniformly been more or less temporary febrile reaction followed by increased cough with marked increase of expectoration containing a greater number of bacilli. In a considerable number of these cases a continuance of the treatment was attended by diminished febrile reactions and decidedly less expectoration with moderate general improvement until apparent immunity or tolerance to the further action of the remedy was acquired by the patient. But in no case did the physical signs of the tubercular disease in the lungs disappear, and after an intermission of ten days or more in the treatment, some of the patients were again found susceptible to the action of the remedy. Consequently we have not yet found a single case of pulmonary tuberculosis in which the remedy could be regarded as having effected a complete cure. In a large proportion of the cases treated in the early stage of the disease, instead of even temporary improvement, the progress of the disease has been accelerated, accompanied, in some, by hæmorrhage, in others by rapid formation of cavities, and in a few by the appearance of albumen in the urine.

Fourth. The foregoing results sufficiently demonstrate that the *Tuberculin* manufactured in Berlin is an exceedingly active poison, possessing a special affinity for tissues affected with tuberculosis, and capable of causing necrosis or rapid disintegration of such tissue in every part of the living body, and consequently its use as an internal remedy will always involve more or less danger to the welfare of the patient.

If the foregoing summary of results thus far obtained is correct, it is obvious that the use of the *Tuberculin* should be restricted to such cases of tubercular disease as are on the surface or have free communication therewith; and the general practitioner should abandon all idea of using it in cases of tuberculosis of the lungs or any of the internal viscera.

ON THE SIGN CALLED "TRACHEAL TUGGING," IN THORACIC ANEURISM.

DR. R. L. MACDONNELL, of the Montreal General Hospital, relates in *The Lancet*, March 7, the clinical aspects of seventeen cases of thoracic disease where "tracheal tugging" was recorded. This sign was first brought forward in 1878, by SURGEON-MAJOR W. S. OLIVER, in *The Lancet*, and his account of it has since been republished in only two text-books, so far as is at present known. In the original publication, the writer suggested the following procedure in the diagnosis of thoracic aneurism: "As the diagnosis of thoracic aneurism of the aorta is often difficult and obscure, notwithstanding the various means we have at our disposal for detecting it, I am desirous of mentioning a method of examination which has afforded me material assistance in diagnosing this disease—or even simple dilatation of the vessel—when it occurs, as is most generally the case, either in the ascending or first part of the transverse portion of the arch; the process is as follows: Place the patient in the erect position, and direct him to close his mouth and elevate his chin to the fullest extent, then grasp the cricoid cartilage between the thumb and finger, and use gentle upward pressure on it, when, if dilatation or aneurism exist, the pulsation of the aorta will be distinctly felt transmitted through the trachea to the hand. The act of examination will increase laryngeal distress should this accompany the disease.

The application of this method of examination has been in vogue in the wards of Montreal Hospital for twelve years, and the sign has come to be known as "tracheal tugging." Its great importance was early recognized by DR. GEORGE ROSS, who in his clinical teaching and published reports of aneurismal cases has been careful to note the presence or absence of tracheal tug. It has always been found to be a reliable sign of aneurism of the transverse arch, and in one case, at least, it was the only positive sign present of an aneurism, whose existence was made manifest subsequently by other signs and symptoms. Where the aneurism is deep-seated and is in contact at all with either the trachea or one of its principal subdivisions there will be a very distinct and unmistakable tugging downward of the cricoid cartilage with each cardiac systole. In some cases the movements of the box of the larynx

have been so well-marked that the pulse could be counted by simply placing the tip of the forefinger upon the *pomum Adami*, and making a slight pressure upwards. One other condition may possibly be mistaken for that under consideration, but a little care will exclude the chance of error: this is when the heart is acting strongly, or when aortic incompetence is present, and so acting as to convey to the fingers, from the adjacent carotids, a considerable amount of rhythmical pulsation. But this will be noted as something different from the downward tugging of the aneurismal sign. DR. MACDONNELL formulates two propositions from his clinical experience, and that of his colleagues at the Montreal Hospital: 1. Tracheal tugging is never present except in aneurism. 2. When tracheal tugging is present the aneurism is so situated as to press from above downwards on the left bronchus, or on that portion of the trachea that is immediately adjacent to it. Of the twenty-five cases in which this phenomenon was examined for and recorded as present or absent, twenty-three were from the hospital, and two were from private practice. In seventeen cases the sign was found. In eight an autopsy was obtained.

SANITARY UNDERTAKING.

The State Board of Health of Pennsylvania has recently issued its Circular No. 31, containing instructions to sextons and undertakers regarding the handling of the bodies of those who have died by contagious diseases. It bears date of December 1, 1890, and comprises in a dozen pages a very full digest of rules and suggestions as to "when, how and where undertakers can and should be sanitarians." One point of prime importance, the avoidance of public funerals after death by infectious disease, is made especially prominent, and it is urged upon all intelligent undertakers that their influence and counsel should always be exerted against publicity and delay in the disposal of the dead in such cases. The undertaker not only owes it to his personal safety to manage such cases with despatch, but the interests of the commonwealth, in checking the dangers from communicable disease, point in the same direction.

The importance of a free use of potent disinfectants is emphasized, and suggestions are offered

tending to the employment of simple, efficient and non-hazardous means for embalming the contagious dead. The circular advises, however, that no process of cadaveric preservation by arsenical preparations, and the like, shall be used unless it shall be known to the undertaker that a written certificate of the cause of death has been given by the attendant physician; and that embalming should never be attempted in the face of circumstances of a suspicious nature. This advice is valid chiefly from the medico-legal standpoint, since death from poison may be covered up by an unduly hasty use of certain embalming methods.

The use of the ice-box is particularly named as an objectionable procedure in the case of contagious deaths. The superficial action of the ice used in the refrigerant process can have little to do towards removing the contagious dangers in these cases, while the process itself is unsafe as regards the undertaker and his assistants, since it involves considerable unnecessary manipulation of the bodies so treated. The circular adds, in this connection, that instances of wanton recklessness have been reported to the Board, in which the ice after use in the box has been thrown in the public street, and the box has been taken the same day into an uninfected house without having been disinfected.

POISONING BY EXALGINE.

A case of poisonous overdosing with exalgine is given in a recent issue of the *British Medical Journal*, by E. E. DYER, M.D. The patient, a man of twenty years, applied for treatment for rheumatism. Exalgine was ordered in doses of grains iijss, in tincture of orange and water, at six hour intervals. DR. DYER was prevented from seeing the man until over forty hours had elapsed, during which time he was told that six doses had been taken. The patient presented the symptoms of carbolic acid poisoning: had been sleeping almost continuously for twelve hours, frequently starting in his sleep, and was very dull and heavy when aroused; complained of pain in the lumbar region. Urine had been passed only twice in twenty-four hours and was of an olive-green color; its specific gravity was high; there was no albumen or blood; deposits of the urates, and not phosphates, were observed. He complained greatly of thirst; the skin was hot and dry, but the highest

temperature obtained was 98° F.; the pulse counted 102, and was full and strong. Salivation was a marked symptom for several days; this was treated by occasional doses of chlorate of potash and subsided soon after the cerebral and renal conditions improved. Otherwise the only treatment mentioned was a diaphoretic and diuretic mixture. The rheumatic and myalgic symptoms appeared to be relieved by the exalgine.

A FORM OF FAITH CURE FOR SNAKE-BITE.

In Southern India, where the natives suffer so much from snake-bite, especially that of the venomous cobra, it is strange that these reptiles are for the most part left in peace, on account of the influences of tradition, superstition and worship of all forms of animal life which forbid their destruction. Even special days are set apart for the adoration of the cobra, when offerings of sugar, milk and other articles of food are made to it. And this is done despite the fact that, in the province of Mysore at least, the Government offers to pay a reward for every snake that is killed and brought in, and thus a superstitious dread of consequences prevents the extermination of these reptiles. The natives believe that their best protection against snake-bites lies in their devotions and offerings, and that if they do not secure immunity against the venom of the reptiles, the fault has been their own, by reason of their inadequate devotions and offerings; which is much the same line of reasoning as that adopted by the unfortunate faith-healers of our own country, who, starting with the proposition that all disease is sin and want of faith, find it easy to charge the latter upon every poor invalid who does not at once declare that he has been healed under the ministrations of the "healers."

EDITORIAL NOTES.

THE BENEFITS OF A SATISFIED STOMACH.—Aside from the well-known aphorism touching the importance of a well-filled stomach upon the joy of the individual, there now comes a confirmation of an opinion which has long been held among physicians, viz., that a full stomach acts as a force against the invasion into the system of the peculiar poisons of many diseases. Experiments have recently been made which go to show

quite conclusively that hunger lessens the ability of the body to defend itself against disease germs. This comes not alone from the fact that the stomach, and sympathizing organs, are actively engaged in that work which they are physiologically destined to perform, but as well from the general effect this may have upon those guiding and governing centres of the central nervous organization, and, also, probably, other factors of which we have but little knowledge.

A NEW INTERPRETATION.—An English quack was recently brought before the police court for practicing without due qualification, who, in defending the use of the characters M.D. and F. R. S. after his name, said they meant "money down" and "Fosterer of Real Science." The individual's genius, however, did not save him for he was fined twenty pounds M.D.

HARPER HOSPITAL, DETROIT.—Staff positions at this institution are hereafter to be had only through the avenue of a competitive examination, and such examination has been thrown open to the graduates of all medical schools. Formerly the positions were accessible but to those holding credentials from the Detroit College of Medicine.

THE WISDOM OF GALEN.—Even upon the subject of lead-poisoning that great medical writer of early ages—Galen—had a clear conception. Thomas Oliver, M.A., M.D., (*Brit. Med. Jour.*) refers to him as condemning the use of leaden pipes, stating that the water which was conveyed through them took on a muddiness from the lead, and produced a kind of dysentery in those who drank it.

FURTHER PRECAUTIONS AGAINST POISONING FROM PRESERVED MEATS.—A timely suggestion has been offered by a German physician that the date of original preservation be stamped upon each and every can or package containing meat foods. It is held that preserved meats, hermetically sealed, may remain wholesome for a year or so, but that there is danger in the use of such foods after this period.

PAGET'S NEW BOOK OF CASES.—Sir James Paget has issued a new book, Longman's publishers, entitled "Studies of Old Case books," in which he discloses somewhat of his literary methods. He began to take notes with the very first case he ever saw, while he was yet an appren-

tice to a medical practitioner of Yarmouth, and he has continued during his forty years of practice the systematic recording of his cases. It is from his numerous volumes of notes that some of his former writings and these newly published "Studies" have been drawn. In the latter, as in earlier books, is displayed the same graceful diction and charm of polished style that have won for him friends among American readers who never saw him. In one of his essays he writes in autobiographic way of "An irregular pulse," his own, which record he closes with the sententious saying: "Few things are more inconceivable than are many things which are certainly true." And on another page when treating of spines that are suspected of being deformed he gives expression to this pithy precept: "Bad postures, long maintained, will bring on bad shapes, and even good postures, maintained with weariness are hardly less injurious." To those who may never hope to see this great surgeon in person this book gives an opportunity to view that winning mental part of him which can be reflected upon the printed page.

"WHEN DOCTORS DISAGREE."—The following resolution was passed at a late meeting of the British Gynecological Society: "That the Obstetrical Society be invited to appoint a sub-committee to act with the sub-committee of this Society to inquire into the cases in dispute between Sir Spencer Wells and Mr. Lawson Tait."

ORNAMENTED SKELETONS.—M. Vassilovski has recently discovered two caves in the Crimea which contain prehistoric remains. These include parts of human skeletons of which some of the bones give evidence of having been painted. It is probable that these relics come down from the time of the Cimmerians of whom Herodotus wrote, regarding their strange rites of sepulture: it was their practice to expose the bodies of the dead at the top of some hill or promontory and there leave them until the bones had been picked clean by birds of prey; then the skeletons were collected and when completely dried were painted over with some mineral pigment.

DANGERS AND DAMAGES DUE TO FACTORY WHISTLES.—Dr. J. H. Albee has won a suit for damages, amounting to \$6,000, for a broken leg, which the jury at White Plains, N. Y., decided was chargeable to the blowing of a steam-whistle,

belonging to the shoe-factory at Chappaqua. Dr. Albee is a Rhode Island physician who had been summering at Chappaqua in the summer of 1888. One day in July he with a friend was driving near the shoe-factory, when the whistle, known as the "seven-mile whistle" was blown; the horse they were driving became affrighted and ran away. The riders were thrown out of the wagon and one of them, the physician, received a serious fracture of the leg. The injured physician in this instance, may or may not have been engaged in professional duty when the whistle shrieked, but he has our sympathy in either case, and we hope that his cause is well and finally won. And for this reason we there highly detest and reprobate the use of these life-endangering steam whistles, which disrupt the atmosphere for miles around. These seven-mile whistles serve no useful purpose that is imperatively demanded by trade or industrial pursuits while they are in many places a daily menace to property on wheels, to limb and life of animals and men, and of the general practitioner, in an especial degree. These frightsome noises have no right to exist.

SCABIES AMONG THE CHINESE.—The *Lancet Medical Review*, February, in some remarks on the low state of medical practice among the Chinese, states that whatever else may be lacking in their system, they do not stand in need of medical aphorisms. These have come down to them from numberless generations and are a large part of their stock in trade. One of these aphorisms, taken at hazard by the *Review*, is: "Out of every ten men eleven have the itch." While there is abundant testimony from other sources that the itch is very prevalent in China, we are forced to the conclusion that as a statistical statement the above aphorism is a failure. There is evidently no need for any parliamentarily inclined individual to rise up and "move to make it unanimous;" the unanimity is there already.

DR. KOCH IN EGYPT.—The overworked Professor Koch has gone on a trip up the Nile which will consume a fortnight or more. It is expected that he will be back again in Berlin directly after Easter to take up his new duties. The *Lancet* correspondent at Cairo writes that Koch arrived there on February 12, looking very thin and ill after five days' sea-sickness and all its attendant evils, and that he avoided all social entertain-

ment, proffered dinners, visits and the like so far as it was possible. Before leaving the city on the 14th, however, Koch found time to visit the Kas-el-Aini Hospital and the German Hospital and to inspect the cases under treatment, at both of them, by tuberculin. At the former institution he found not less than twenty cases of phthisis, lupus and tuberculous joints on which to lecture briefly as to the time and method, and quantity for the injection. He inclined to criticise here, as elsewhere, those operators who use the remedy with too much caution. He thought the doses were not infrequently too small and at too long intervals to procure the desired result.

Regarding the tourist-season on the Nile, the writer adds that despite the opening of new hotels and a new line of Nile boats, Cairo has never been so overcrowded before as it has been during the past winter; during four days of the week when Koch passed through not less than 500 travelers left the capital—250 to go up the Nile and as many more going in the other direction to the Holy Land, Athens, Rome and other points.

A STRIKING DEFINITION.—Dr. Holmes in his "Over the Teacups" defines a crank, "as a man who does his own thinking." They are called cranks because they "make all the wheels in all the machinery of the world go round."

AMERICAN ACADEMY OF MEDICINE.—The sixteenth annual meeting of the American Academy of Medicine will be held at Washington, D. C., May 2 and 4, opening at 3 P.M. May 2. As it will be just previous to the sessions of the American Medical Association, members will be able to attend both meetings.

MEDICAL ITEMS.

IDIOSYNCRASY TOWARDS FRUIT.—Dr. S. V. Clevenger, of Chicago, mentions a case (*Times and Register*) of marked aversion towards all varieties of fruit. The person is a young lady, now twenty years of age, and has always suffered from this peculiarity. She is sickened at once upon the sight or odor of apples, peaches, pears, etc., and she abhors sweets of all kinds. Dr. Clevenger desires that physicians having cases of a similar character should make them known to the medical world.

IOWA STATE MEDICAL SOCIETY.—The fortieth annual session of this Society will be held at

Waterloo, Iowa, Wednesday, Thursday and Friday, April 15, 16, 17. A cordial invitation is extended to the profession. An excellent programme has been prepared. Let every county or district society send a full representation of new delegates, and let the permanent members be in full force. The Chairmen of the different Sections and all officers of the Society are requested to meet in Waterloo on Tuesday preceding the annual meeting, to confer with the President, Dr. W. D. Middleton, and the Chairman of the Committee on Arrangements, Dr. D. W. Crouse, at such place as the latter may designate, for the purpose of arranging the programme and attending to other business matters. Reduced rates have been granted on all roads in Iowa. When you buy your tickets be sure to ask the agents for certificates that you have paid full fare one way. Present these early in the session for Secretary's signature. Any further information will be cheerfully given by C. F. Darnall, West Union, Secretary; W. D. Middleton, Davenport, President, or D. W. Crouse, Waterloo, Chairman of Committee on Arrangements.

DECREASE IN CANDY POISONING.—Owing to the increasing and constant warfare by the National Confectioners' Association, there has been a very marked decline in the number of instances of untoward effects from candy eating.

THE NATIONAL ASSOCIATION OF RAILWAY SURGEONS will convene at Buffalo, N. Y., Thursday, April 30, 1891. This is a change of one week from the time previously announced, the change having been made so as not to conflict with the dates covered by the meeting of the American Medical Association.

AN EVIDENCE OF FAITH.—That faith as to the ultimate outcome of the Koch treatment strongly abides in the breasts of those constituting the municipal authority of Berlin is indicated by the movement now being made to found a home for convalescents who have undergone the new process of cure.

A NEW MEDICAL LIBRARY BUILDING.—In connection with the Boston City Hospital a building was recently opened and occupied for library purposes. The general arrangement is quite convenient, and the event of the opening was made the occasion of a hearty reciprocity of good feeling between the members of the various hospital staffs in the city.

TOPICS OF THE WEEK.

PROFESSOR KOCH'S TREATMENT OF TUBERCULOSIS.

Professor Virchow, at the meeting of the Berlin Medical Society on February 25, again referred to Koch's treatment, and showed some specimens in illustration of his remarks. He doubted whether the statement by Dr. B. Fraenkel, as to the duration of miliary tubercle, based on inoculation experiments, was correct—namely, that a period of three weeks is required for its development. The question was one to be decided by clinical observers, for it could not be determined by pathologists. If one were to admit that in all those cases in which miliary tubercle is found this has been present before the injections were practiced, then a much longer extension must be given to the duration of miliary tubercle than has hitherto been assigned to it. A distinction in this respect must be made between local tuberculosis and the general acute disease which creates such marked constitutional disturbance. He detailed a case of pleuritic effusion under the care of Professor Leyden, in which phthisical signs, with laryngitis and fever, developed whilst under treatment by Koch's injections, death supervening four weeks after the first injection. In this case there was very marked general miliary tuberculosis, submiliary granulations occurring in liver, kidneys, thyroid, larynx, and in parts of the peritoneum, including the recto-vesical pouch, as well as in the lungs, which were also the seats of old apical mischief. Here was a case which certainly did not come under the class referred to by Dr. Fraenkel, for it had been long under observation and had been injected before the supervention of the acute tuberculosis. Professor Virchow also showed a lung from a patient who had received eight injections, which presented a large caseous mass in process of separation, and an intestine exhibiting a very marked eruption of tubercles and implication of the lacteals in the vicinity of ulcers.

Professor Cantani, of Naples, in giving the results of his experience with Koch's remedy (*Berl. Klin. Woch.*, No. 9), points out that the important part of the method is the production of local reaction, which in some cases occurs without any general febrile disturbance. This local reaction, he said, is nothing else than a quickening of the natural processes whereby the organism seeks to get rid of the *materies morbi*. He found more marked improvement in cases where there was no fever and only slight local reaction—cases in which the commencing doses were very small, and their repetition with slight increase in quantity made at some intervals. He further explained that many of the alleged dangerous results of the treatment are prone to occur in the spontaneous course of tubercular disease, but may occur more readily and rapidly from the hastening of the necrotic process by the injections. Nor should the result of every case that is fatal whilst undergoing this treatment be assigned to the latter; and he did not doubt that when the time came for a full survey it would be found that the favorable results would counterbalance the unfavorable. As to the prospect of Koch's fluid curing tuberculosis, Pro-

fessor Cantani remarked that the changes observed in lupus were very hopeful. In the lungs the physical signs denote the occurrence of similar changes to those observed in lupus, and the increased bacillary expectoration was evidence of the focus being destroyed. But the impediment to the free removal of the necrosed area in the case of the lungs was against marked progress, although this was noted in some cases. The laryngeal cases showed more obviously the local improvement. Professor Cantani points out that phthisis embraces not only tuberculosis, but other septic processes due to the presence of pyogenic organisms; so that in advanced cases little can be expected from the treatment, which in such must be followed with the greatest caution, if at all. He did not think the time had arrived for a definite conclusion to be formed as to the efficacy of the method in phthisis, and deprecated too great enthusiasm on the one hand and depreciation on the other as contrary to the interests of truth. The remedy was new and its efforts striking, but it must be further studied before its practical value is appraised. At any rate, Koch had shown the path to be taken by bacteriology in the future, and the progress of knowledge would cause its further extension.—*The Lancet*.

MEDICAL MEN AND LITERATURE.

Literary production in other than professional fields has in all ages divided with more purely technical studies the power of attracting the mental energies of medical men. Such names as those of Roger Bacon, Sir Thomas Browne, Locke, Garth, and others have indeed so shone in the fame of letters that in their case an original connection with medicine has almost been forgotten. In these days the zeal for learning follows a more exclusively practical and scientific tendency. As if in harmony with the laws of the circulation, the cravings of the medical mind commonly find satisfaction within the round of its most familiar occupations. There are, however, not a few exceptions to this rule. We have not yet lost the medical poet or philosopher, nor have the efforts of romance in prose been unassisted by practitioners of our art. To employ thus the precarious leisure of routine in practice cannot but refresh the mind of those most nearly interested, while recent experience might also be shown to prove that efforts thus applied have not been fruitless in refreshing the intellect of the reading community. Some faults might naturally be expected in the productions of a medical writer. Among the chief obstacles to his success may be numbered a too didactic style, a philosophic heaviness, above all, a tendency to excess in realism, particularly if engaged upon that now all-popular and most profitable form of composition, the novel. An error of discretion, indeed, may sometimes lead to serious embarrassment. Take, for example, the case of a medical novelist in France, who was lately called upon to answer the allegations of an indignant husband that his wife's morbid state was exactly reproduced in the heroine described by her doctor, who was therefore liable for a breach of professional secrecy. The case might well have been one in which the cap of the proverb was found to fit a head for which it was not made, but it may

serve, nevertheless, to accentuate the dislike to an exact description of morbid states and symptoms in which we must admit a share with many general readers. A high professional standard alike in literary taste and in true medical propriety is, we take it, best maintained by those who can discreetly separate what are in them related faculties, and be medical in their medicine but scholarly in letters.—*The Lancet*.

OFFICIAL REGULATIONS AS TO TUBERCULIN IN GERMANY AND ITALY.

The Prussian Minister of the Interior has given permission for the use of Koch's remedy for tuberculosis in prisons, under the following conditions: (1) A special department must be established for the purpose. (2) The medical officer in charge of these cases must reside in the institution. (3) In the case of patients with pulmonary phthisis, only those in whom the disease is recent, or who seem in other respects particularly suitable subjects, must be subjected to the treatment; and (4) the remedy must in no case be used against the patient's will. Surgeon-General von Coler has issued an order regulating the use of Koch's remedy for tuberculosis in the Prussian army. Each garrison hospital is to be provided with a special department in which the treatment can be carried out, and to this all cases of tuberculosis in soldiers belonging to the corresponding district corps which appear suitable are to be sent. The tuberculosis department is to be isolated from the others, and must be provided with all the necessary equipment for scientific observation. At a recent meeting of the Italian Superior Council of Health, the President, Professor Baccelli, presented a report on the Koch treatment, which was referred to a Special Committee. This committee has now submitted the conclusions at which it has arrived to the Council. The following is a summary of the committee's report: (1) The instruction issued by the sanitary authorities on December 14th, provisionally restricting the use of Koch's fluid to university and hospital clinics, is approved of. (2) Circumstances are now changed. The numerous experiments made in Italy and in other countries, and particularly those of Professor Baccelli himself, have better defined the true value of the remedy, and shown the indications for its use, and the possible dangers attending it. The committee therefore has no hesitation in proposing that the remedy be entrusted to the hands of individual members of the medical profession, just as they are allowed to use other remedies not less useful and at the same time not less dangerous. (3) Compared with other remedies in the pharmacopœias, however, Koch's fluid presents this difference while the purity and quality of these can always be kept under strict control, in the case of the latter there is no other guarantee than the fact of its coming from the institute in which it was originally discovered. The committee therefore considers it indispensable that the fluid should be introduced into Italy only by the central authority, by which also it should be distributed under such conditions and with such safeguards as may be thought advisable. (4) Lastly, the committee recommends that in distributing the fluid the central authority should at the same time issue the necessary

instructions for its use, and should request the medical practitioners to whom it is supplied to report all the cases in which they employ it, and the results obtained. The committee's report was unanimously adopted by the Superior Council of Health.—*Brit. Med. Journal*.

THE BEQUESTS UNDER THE FAYERWEATHER WILL TO HOSPITALS.

The will of Daniel B. Fayerweather, late of New York City, by arrangement with counsel for the contestants has at length been admitted to probate. The error of the deviser was the having made too low an estimate for the adequate support of his widow. The exact terms of the settlement are not known to the public beyond the increase of income and a cash payment, both in favor of the widow. The estate is supposed to be worth five and a half millions of dollars, which after certain gifts and bequests leaves a remainder to be divided into ten parts: one to Yale, one to Harvard, one to Princeton, one to Columbia, one to the Presbyterian Hospital and five to the Woman's Hospital. As now arranged St. Luke's, the Presbyterian and the Manhattan Eye and Ear Hospitals receive each \$50,000; the Woman's \$210,000; the New York Eye and Ear Dispensary, the Manhattan Dispensary, the Montefiore Home for Chronic Invalids, the Mount Sinai, the Methodist (Brooklyn) and the New York Cancer Hospitals receive each \$25,000, while the Society of St. Vincent de Paul receives \$50,000. It is shown by the tabulated statements as given by the secular press that the \$25,000 bequests are gains to the institutions named by absolute deed of gift. So also the Society of St. Vincent de Paul gains its full amount, while St. Luke's, the Presbyterian, the Manhattan Eye and Ear Hospitals gain severally \$25,000 apiece, the Woman's Hospital \$200,000 and Mount Sinai \$15,000. While, on the whole, this estate so far has made the greatest gifts in this country for benevolence and education, we cannot but deplore the ignoring of a profession which has rendered all such charities possible. Truly there are many libraries in and about the cities and towns which might have been medically reinforced with profit to not over-wealthy physicians. Still, we are not inclined to jealousies.

LIVING MICRO-ORGANISMS IN TUBERCULIN.

The Russian commission for the study of Koch's method, headed by Prof. Wissotsky, received two packages of tuberculin, one from Libberts and the other from Guttman. Both were found to contain living microorganisms. From this the commission concluded that it would be wise to confine their researches to experiments upon animals and to bacteriological studies. Three packages secured later contained living microorganisms and, like those earlier received, were strongly alkaline in reaction.—*La Semaine Médicale*.

MEDICAL PRACTITIONERS IN PARIS.

The number of medical practitioners in Paris is stated to be 2,200. As the population of the French capital is 2,700,000, this gives a proportion of one medical man to about every 1,200 inhabitants.

PRACTICAL NOTES

ACUTE CYSTITIS.

Dr. A. W. Marsh, in the *Therapeutic Gazette*, strongly recommends the use of the following formula, requiring that *distilled* or rain water be used in its preparation to prevent the formation of oxalate of lime. The relief from pain is prompt and the results exceedingly satisfactory :

- R. Acid oxalic, gr. xvj.
Syr. aurantii cor., ʒij.
Aquæ pluv., q. s. ʒiv. ℥.
Sig. Teaspoonful every four hours.

FOR THE GRIPPE.

Dr. E. R. Palmer, of Louisville, says that with the recurring prevalence of the so called *grippe*, he suggests the following as a specific for adults in such cases :

- Salol, ʒij.
Phenacetin, ʒij.
Quinæ salicylat., ʒj.
M., fl. cap. xx. Sig. Two every three hours.
—*American Practitioner and News*.

WARTS.

- R. Hydrarg. chlor. corros., 1 part.
Collodion, 30 parts. ℥.
S. Apply once daily about the base of the wart.
—*Cincinnati Lancet-Clinic*.

AN INJECTION FOR GONORRHOEA.

Prof. Keen gave the following formula to be used as an injection in gonorrhœa :

- R. Zinci sulphat., gr. xvij.
Catechna.
Matico, ʒā f ʒjss.
Glycerini.
Aquæ, ʒā q. s. ad. f ʒj.
M. S.—Inject f ʒss, retaining each injection for at least five minutes.
—*Times and Register*.

CREOLIN IN ACUTE GASTRO-ENTERITIS.

Schwinz has employed this drug with success in the following formulæ.

- R. Creolin, ℥ij.
Syrup althæa, ʒv.
Aq. cinnamonii, q. s. ad. f ʒij. ℥.
S. To a very young child a small teaspoonful hourly. To older children the drug may be given in a powder.
R. Creolin, ℥xv.
Sacchari alb., gr. lxxv. ℥.
Divide in Chart No. X.
S. One or two powders daily.
—*Wiener Medizinische Wochenschrift*.

FOR ASTHMA.

Dr. W. T. Plant, of Syracuse, N. Y., says that an asthmatic neighbor of his gets so much relief

from inhaling the smoke of a teaspoonful of the following combination that he wants all other chronic asthmatics to know about it :

- B. Stramonium leaves, ʒā ʒiv.
Green tea dust, ʒā ʒiv.
Lobelia, ʒss.
Mix together and wet up with a saturated solution of nitrate of potassium. Dry thoroughly and keep in a close can or well stoppered bottle.

—*American Practitioner and News*.

FOR ECZEMA, ETC.

In the case of a child 7 months old presenting the following symptoms : The food taken passed by the bowels undigested ; there was obstinate constipation ; the patient also had an eczematous rash upon the face. Dr. Rex prescribed the following treatment :

- R. Resinæ podophylli, gr. j.
Alcoholis, ʒv.
Aquæ, ʒij.
℥. S. In drop doses.
For the eczema of the face :
R. Acid. salicyl., gr. x.
Adipis, ʒj.
℥. S. Apply locally.

For a case of pharyngitis complicated with bronchitis, Dr. Brinton gave the following formula :

- R. Ammonii chloridi, gr. v.
Vinii antimonii, ʒtt. x.
Vinii ipecacuanhæ, ʒtt. x.
Mist. glycyrrhizæ comp., ʒj.
℥. S. Every three or four hours.
—*Times and Register*.

CROUP.

Dr. J. B. Johnson uses the following :

- R. Aquæ destillat., ʒj.
Potass. chlorat.
Potass. iodid., ʒā ʒj.
Emuls. arabicæ, ʒj.
Mucilag. acaciæ.
Ext. ipecac., fl.
Olei copaibæ, ʒā ʒj. ℥.
S. Shake well. Dose, a teaspoonful every ten minutes, to an infant of 8 months, till free vomiting ceases ; and then continue the same dose every half hour or hour until the disease is cured. The dose must be given according to the age of the child.
—*New England Med. Monthly*.

CYSTITIS.

This remedy is highly spoken of by a number of practitioners in genito-urinary diseases, and more especially in cases of cystitis, following operations, or from other causes. One of the best formulas is that of Dr. Hal. C. Wyman, which is as follows :

- R. Fl. ext. pichi, ʒ.
Ft. ss. nitr., ʒj.
Simple elixir, ʒij.
℥. Sig. Teaspoonful once in two hours.
—*St. Louis Med. and Surg. Journal*.

SOCIETY PROCEEDINGS.

The Clinical Society of Louisville.

Stated Meeting January 13, 1891.

THOS. P. SATTERWHITE, M.D., PRESIDENT, IN THE CHAIR.

DR. L. S. MCMURTRY presented a specimen from

A CASE OF EXTRA-UTERINE PREGNANCY

with the following history:

Mrs. S. E. M., age twenty-seven years, married nine years. Eight years ago she suffered an abortion at three months, has had uterine disease ever since, and has been sterile. She missed the menstrual period in November, and on December 7th called to see her physician, Dr. George W. Griffiths. Her complaints were of general abdominal pain and discomfort. She again called on Dr. Griffiths on December 11th. On the 13th, two days later, she had a violent paroxysm of pelvic pain localized on the right side. Dr. Griffiths saw her soon afterward and administered a dose of morphia. She was relieved for the time. On the evening of the 18th Dr. Griffiths summoned me to meet him in consultation, and expressed the belief that abdominal section was indicated. The abdomen was swollen and tender with increasing peritonitis. There was a bloody flow from the uterus. The patient was pallid as from *post partum* hæmorrhage. Vaginal examination showed the uterus pushed to the left side and the pelvis choked with effusion. The pulse was 134, small, the pulse of hæmorrhage. The bowels had not acted for four days. We gave an energetic purgative, and arranged for operation the following morning.

Early on the morning of the 19th I opened the abdomen. Dr. J. W. Guest gave ether and Dr. Griffiths assisting. On opening the peritoneum a large quantity of blood flowed out over the table. More than a gallon of blood-clot was removed. The fetal ball was on the right side. The right appendage was tied off close to the uterus, the cavity irrigated with warm distilled water, a glass drainage-tube placed, and the abdomen closed. When put on the table the pulse was 140 and quite feeble. The appendage on the opposite side was not removed, as I feared to prolong the operation. The operation was concluded in thirty minutes.

The specimen is of great interest. You will recognize here the ovary, and here the ruptured Fallopian tube and the fetal envelopes. From this poured the fearful hæmorrhage, which invariably ends in death if not arrested by surgical interference.

This is the first case of extra-uterine pregnancy, so far as I can learn, operated upon in Louisville by abdominal section at the time of rupture. The

success of the case is due to Dr. Griffiths' recognition of the gravity of the situation, and advice for immediate operation.

Ectopic gestation is a very common accident. Hundreds of women perish annually from this cause because it is not recognized. Dr. Formad, the well-known pathologist of the University of Pennsylvania, as coroner's physician for Philadelphia, states that in one year he found post-mortem nineteen cases of ruptured ectopic pregnancy unrecognized. The symptoms are those of shock, internal hæmorrhage and peritonitis. The patients exhibit a history of sterility and peri-uterine inflammation. The fertilization of the ovum in the Fallopian tube is due to a desquamated salpingitis by which the lining of the tube is deprived of its ciliary epithelium. Extra-uterine pregnancy is almost invariably tubal. The tube ruptures about the twelfth week. It may rupture through the free surface of the periphery of the tube directly into the peritoneum, as in the specimen here presented. This is a deadly accident, if the hæmorrhage is not arrested by surgical means. The rupture may occur in the portion of the tube included between the folds of the broad ligament, allowing the foetal structures to escape into the cavity of the broad ligament. These latter are the cases of extra-uterine pregnancy which go on to a viable period. Extra-uterine pregnancy until very recently was not understood in its pathology, and was classified and treated as accidental hæmorrhage, hæmatocele, etc. It is now well known that most cases of hæmatocele so-called, are in reality cases of ectopic pregnancy. The treatment in all cases should be immediate abdominal section. The uterine appendages of both sides should be removed, inasmuch as the predisposing salpingitis is symmetrical. I have now operated in three cases within the last two years for ruptured tubal pregnancy, and all have recovered. The only safety in such a condition is immediate operation. The diagnosis before rupture is practically impossible. When rupture occurs the indications for surgical interference are as positive as in treating a wound of the brachial artery.

DR. GEORGE W. GRIFFITHS: I can add very little to the history as already detailed. As soon as the symptoms of shock and hæmorrhage appeared I advised operation. I have witnessed a great many bloody operations, and in my work as railroad surgeon have seen many severe accidents, but I must say that when the abdomen was opened in this case and the blood gushed out it was the most formidable operation I have ever seen. I saw the patient to day and she is entirely healed and well, though she is pale from the severe loss of blood. She went out to the table and ate with the family to-day for the first time, three weeks after the operation.

DR. I. N. BLOOM: Had the symptoms been

more pronounced the night you first saw her would you not have operated immediately?

DR. McMURTRY: Operation would have been immediately done had the diagnosis been absolutely positive. That is, of course, impossible before the abdomen is opened.

DR. J. A. OUCHTERLOXV: I do not know when I have seen a specimen and heard a report so interesting and of such great practical importance as this. It brings vividly to my mind a number of cases I have seen during the past thirty years, which were diagnosed by myself and others with whom I was associated as pelvic hæmatocele, and at the same time there was always something inadequate in the diagnosis, and it seemed incomprehensible why there should be such terrific hæmorrhage and such profound shock. It is a great satisfaction to know that light has been shed upon this important and perilous condition, and that we can predicate accurately the pathological condition. Cases that formerly were considered to be cases of hæmatocele are now known to be ruptured ectopic pregnancy. A most pleasant reflection is the fact that these cases can be so successfully managed by prompt surgical interference. It gives confidence and hope to the medical attendant, and it is a warning, and a solemn one, to lose no time in adopting the prompt course of procedure taken in the case just reported.

DR. F. LEBER: Many cases of hæmatocele recover by absorption, without operative interference.

DR. McMURTRY: When rupture occurs through the free surface of the tube it is a deadly accident from hæmorrhage unless treated by surgical means. If the rupture, however, takes place into the folds of the broad ligament the effusion may become absorbed, or the foetus may develop there, forming abdominal pregnancy and going on to and beyond full term. The foetal mass may break down and suppurate, discharging through the rectum or the bladder. In any contingency the safest result is secured by abdominal section. There is less danger in abdominal section according to modern methods than by taking the risk of these several terminations.

DR. T. P. SATTERWHITE: It is the first specimen of the kind I have ever seen. I agree with the essayist that it is an exceedingly difficult matter to diagnose absolutely that condition of things. In several cases, which I have seen with Dr. McMurry, I considered his advice to open the abdomen unwise, but in every instance have been convinced that it was the correct course to pursue.

DR. F. LEBER: I was asked to see a young man who was injured out West. It was

A CASE OF CRUSHED FOOT.

When he arrived at his home in Louisville he had been treated for three weeks. The foot was

in a very bad condition, and I advised amputation above the ankle joint. This was refused, and the case was treated by another physician. I was again asked to see him, and again suggested amputation, which was refused. I report this case to say that in my opinion in all such cases amputation should be done above the ankle joint. In my opinion Chopart's amputation has never been satisfactory. I recall to mind a case left in my care by the late Dr. Cowling, in which Chopart's amputation was done. It left a miserable pointed stump. I treated it for months with various devices, but never succeeded in getting a good stump. I was compelled finally to amputate. My experience during the war convinced me that none of these operations below the ankle gave such good results as amputating above the ankle.

DR. J. W. GUEST (by invitation): I had two cases of this description in the hospital. Both healed by primary union and were discharged at the end of one month. It seems to me that in doing Chopart's amputation you save the ankle-joint as a natural joint, which is better than an artificial one. At each of these operations tenotomy was performed to prevent the stump from pointing. My experience with Chopart's operation has confirmed that operation in my confidence. It gives a good solid base for a foot independent of any artificial foot.

DR. I. N. BLOOM: I wish to make a report of a case, although one case can not determine the method of treatment for a given disease. I recently had

A CASE OF SWEATING OF THE FEET.

The means I employed in this case were very simple. I had the patient bathe the feet in a solution of bichloride of mercury, 1 to 1,000, morning and evening. After rubbing the surface carefully so as to remove the dead epidermis macerated by the sweat, I directed the following course, which is partly though not wholly original. I had a plaster sole, partly soaked in a bichloride solution, put in the shoe, the solution being 1 to 1,000. After drying the sole and placing it in the shoe, I sprinkled it with powdered boric acid. As regards the advantage of this method of treatment, there is much diversity of opinion. In this case the result was quite satisfactory. If this treatment were uniformly successful it would point to a microörganismic origin for the disease rather than a neurological. My experience has been too short to determine, but this I know, that in many cases, especially of the lighter forms, it is of nervous origin. I have always found it much easier to cure simple hyperidrosis of the feet than of the hands, and have found that Hebra's method with diachylon ointment is the only one promising any hopes of success. I have tried many other means recommended by worthy men, but

always had to return to the diachylon. The inconvenience of this latter method is great, but patients bear it, or will bear any treatment that will help to get rid of the disagreeable disease. This is especially true of women.

DR. WM. CHEATHAM: I have seen recently three cases of congenital pharyngeal fistula. They all opened on the left side of the larynx. Colored fluid, such as the methyl-violet solution, injected into the fistula, passes into the pharynx; a peculiar viscid fluid, with air bubbles, escapes when pressure is made on the tract. These cases are very difficult to heal, as the course of the fistula is so sinuous, and the healing must commence at the pharyngeal end; the best method to close them is by the galvano-cantery wire.

DOMESTIC CORRESPONDENCE.

LETTER FROM BALTIMORE.

(FROM OUR REGULAR CORRESPONDENT.)

The Winter Course of Lectures at Johns Hopkins Hospital—Professor Welch on the Etiological Relationship of the Klebs-Loeffler Bacillus to Diphtheria—Professor Osler's Researches upon the Amœba Coli—The District Club—Miscellaneous Items.

Among the special courses given this winter at the Johns Hopkins Hospital are the following: "Valvular Diseases of the Heart" and "Practical Aspects of Cerebral Localization," by Prof. Osler; "The Pathology of Bright's Disease," by Prof. Councilman; "The Historical Development of Bacteriology" and "The Development of Modern Views on Immunity," by Dr. Abbott; "Special Subjects in Bacteriology," including "The Relation of Bacteria to the Infection of Wounds," by Prof. Welch, and special subjects connected with mental disease, gynecology and surgery, by Professors Hurd, Kelly and Halstead.

Contrary to the views of J. Lewis Smith, that "the Klebs-Loeffler bacillus has no more significance as a cause of diphtheria than the micrococcus of Oertel," and of Oertel, who "admits that the theory that diphtheria is due to bacteria, though plausible, is not proved" (Keating's Cyclopædia of Diseases of Children, Vol. i, p. 587, etc.), Professor Welch considers the evidence of the etiological relationship of this microorganism to diphtheria as now complete. He finds it always present in examination of the pseudo-membrane, and he has isolated, cultivated and successfully inoculated it upon animals. To all appearances, the membrane to which it gives rise is identical with that from which the infecting material was obtained. The bacillus in question, a rod-shaped organism, of about the same length as the bacillus tuberculosis but twice its thickness, is motionless, does not form spores, is nota-

ble for variety of shape, being sometimes clubbed or pear-shaped, sometimes of a dumb-bell form, and sometimes swollen in the middle. Often it is dotted, suggesting spores, but the effect of moderate heat upon these dots shows that they have not the vitality of spores. The fact that the bacillus has been discovered in other affections, as measles and scarlet fever, and even very exceptionally in the mouth in health, upon which so much stress has been laid, offers no obstacle, in Prof. Welch's view, to its acceptance, for many facts show that something more is required than the bacillus, viz.: an abrasion or a catarrhal condition of the mucous membrane. Without some such favoring condition, the bacillus will not gain an entrance and find a nidus for its lodgment and development. Prof. Welch gave minute directions for taking the membrane from the throat for examination and for the cultivation of the organism. He laid great stress upon the value of such examination for diagnosis, considering it to be the duty of every physician to fit himself for making it whenever the occasion requires.

Prof. Osler continues his researches upon the amœba coli, and a short time ago exhibited microscopic specimens from his tenth case. Hundreds of these giant amœbæ, which are nine or ten times as large as the white blood corpuscles, were seen upon the slide, undergoing continual change of shape. The last nine cases were indigenous. In more than one he was able to make the diagnosis of abscess of the liver with perforation into the lung, merely from finding the organism in the sputa. Such sputa present a very characteristic appearance, he says.

The Historical Club at the Hopkins continues to be well attended and to present interesting programmes. Many outside physicians interested in such subjects attend its meetings. In a sketch of John Archer, M.B., by Dr. J. M. T. Finney, the following interesting account of the circumstances attending the awarding of the first medical diploma in America is given: "In June, 1768, at the Commencement of the College of Philadelphia, afterwards the University of Pennsylvania, medical degrees were conferred for the first time in the New World. On that occasion there were ten candidates for degrees, their names being Archer, Carroll, Duffield, Potts, Elmer, Fullerton, Jackson, Lawrence, Tilton and Way. At that time, seven years before the War of Independence, the feeling among many of the colonists was still strongly in favor of the mother country on all occasions. Among their number were the faculty of Philadelphia College, all of whom had received their medical education in England. Immediately a controversy arose as to who should receive the first medical diploma on this side of the ocean. The faculty, animated by the feelings alluded to, declared their intention of conferring it upon the only Englishman

among the candidates—Potts by name. The other candidates protested; still the faculty would not yield. But the former, who had already passed their examination, demanded unanimously, with the single exception of the Englishman, certificates of their having so passed, at the same time expressing their determination to repair at once to Princeton, present their certificates to the faculty there and request diplomas from them. The idea of losing nine out of ten members of this, their first graduating class, was a little more than the faculty could stand, so they agreed finally to let the young rebels arrange the matter among themselves, whereupon they agreed to receive their diplomas in alphabetical order, except that they generously allowed the Englishman to come fourth in order, whereas a strictly alphabetical arrangement would have placed him eighth in the list. As Dr. A.'s name headed the list, he was the first of the candidates to receive his diploma. In the published history of the University, the list of graduates is printed in the order given above. The Princeton College and Philadelphia Medical College diplomas of this quite remarkable man are to be seen at the Medical Library room in this city, also his old mortar, medical ledgers and a pocket-case of silver-mounted surgical instruments which he used in his practice, as well as the proceedings in manuscript of the Hartford County Medical Society, held in his office in old Medical Hall over a hundred years ago."

Dr. Osler spoke of the first American surgery, published in 1776, and of its author, Dr. John Jones, who died in 1791 in Philadelphia. It was used as a manual by the medical officers during the Revolution. Dr. Hoch gave extracts from the "Ebers Papyrus," the oldest medical writing extant. It was written in the Coptic language, and was discovered in Egypt. It is preserved in the library at the University of Leipzig, stretching through two rooms, and is covered with glass for protection. It is still neat and clean. Its only medical value appears to be its antiquity. Dr. Kelly drew attention to a trial for witchcraft for deformed genitals, which took place in Virginia in 1705, and is given in "Howe's History of Virginia;" he believed it to be the only case of the sort reported in the Southern States.

Dr. John N. Mackenzie reported recently a case of tuberculosis of the lip in a negro, aged 35. The man first noticed an ulcer on the centre of the lower lip four months before he came under notice, having previously suffered from symptoms of pulmonary and laryngeal trouble. One month later he had noticed another ulcer at the right angle of the mouth, extending slowly and invading the inner surface of the cheek. When he came under notice (he was seen at the dispensary only twice, as he died shortly after), the central ulcer was slightly less in size than a silver quar-

ter, it was granular, oval, on one side shading off into the surrounding tissues, and on the other presenting a more or less clearly marked beveled border; its base consisted of flabby granulations, some resembling small tubercles, was covered with muco-pus, and had a worm-eaten appearance. The other ulcer presented similar appearances. The lip was swollen to three or four times its normal size. The tuberculous nature of the ulcer was confirmed by microscopic examination. The larynx showed the usual signs of tuberculous disease. The great variety of these cases was pointed out: of 114 cases of buccal tuberculosis collected by Delavan, in 1886, only two were seated on the lip. H. Mackenzie, of Edinburgh, refers to a third, a fourth was seen in Vienna, but not reported, and Prof. Welch had met with a fifth. As pointed out by Prof. Welch, it is possible that some of the cases reported as epithelioma of the mouth were of this nature.

Dr. Charles E. Simon, Assistant Physician at the Hopkins Hospital, having tested the urine in almost every case occurring in that institution, and also cases in health, has not obtained Ehrlich's test (the so called diazo-reaction) in any cases except phthisis and typhoid fever. Contagious diseases were not included in his researches.

A department for teaching the science and practice of invalid cooking has been organized in the Johns Hopkins Hospital Training School for Nurses, under Miss Hampton, the Superintendent. A competent teacher was secured from the Boston Cooking School. Two pupils are sent to her for a month at a time and their hours of duty are from 7:30 A.M. to 5:30 P.M. The chief portion of the instruction is given in the cooking school kitchen which is in a room convenient to the wards. The method of preparing about 150 different articles of sick diet is taught during the month, and all the beef tea, chicken-broth and mutton-broth for the use of the hospital are made each morning by the pupils. Theoretical instruction by lectures is given in the afternoon. Each pupil is required to give a practical test of her proficiency at the end of her month by preparing as large a number of dishes without aid from her teacher or notes as possible. There are also oral and written examinations. The approximate cost of establishing and providing such a school for the first year is \$600, after that \$500 or less. Itemised, the expenses are: complete outfit of utensils, \$70; range, \$20; tables \$8; dresser, \$3; china closets, \$3; sink, \$15; other details, \$5; teacher's salary, \$30 per month; cost of teaching material per month, \$5 to \$8; fuel, \$1.50. The school has been working for six months and its value has been demonstrated.

The University of Maryland Training School for nurses is in a flourishing condition, under the able direction of Miss Parsons, Superintendent, an English nurse trained at St. Thomas' Hospital,

London, and in the Egyptian campaign under General Wolseley. She was decorated by the Queen with the royal red cross. It was established primarily to supply nurses to take the place of the Sisters of Mercy, who left the University Hospital two years ago, and the present class (the second) consists of twenty students. A concert and tea were tendered to the nurses on the 25th ult. by the wives of the members of the medical faculty. Notwithstanding the unfavorable weather, a large and distinguished company assembled, comprising many of the élite of the city. The interior of the hospital was beautifully decorated with potted plants, and the whole building with its bright and cheerful rooms, and its spotlessly clean corridors was thrown open for inspection. In the nurses' sitting-room a table was spread with good things, lit up by wax candles in shining candelabra and under yellow shades. After addresses by Prof. Chew and Miss Parsons, outlining the work and methods of the hospital and training school, a delightful musical programme was rendered by several of our best vocalists, including two of the alumni of the University, Drs. Hopkinson and Sanchez. The establishment and success of this school have been most gratifying to the authorities of the University; it not only supplies the nursing service of the hospital in the most effective manner, but promises likewise to supply a much-felt want in the community. The nurses have a thorough training both in the general and in the Free-Lying-In Hospital of the University near by.

On Thursday, January 15th, in the presence of a number of city officials and several members of the medical profession, the new morgue was turned over to the Health Commissioner by the Inspector of buildings. Dr. Robt. Health Commissioner, made an address in which he stated that the small amount which had been appropriated (\$4000) had been judiciously spent, after due examination of similar structures elsewhere, and he did not believe there was a building in the country better adapted for the purpose of a morgue than this one. It has an office, an inquest room, a cold storage-room containing a refrigerator capable of accommodating five bodies, an autopsy room, a room for surgeon's instruments, a cabinet room for the effects of the deceased, an elevator, closets, etc. A lunch was served at the close of the exercises. The cause of the medical education of women, which received such an impulse by the action of the Johns Hopkins Hospital authorities, has been further strengthened by the able advocacy of Cardinal Gibbons, the Roman Catholic Archbishop of Baltimore. In a letter recently published, he says there is no obstacle in ecclesiastical or canon law to the study and practice of medicine by women. "I do not hesitate to say," he says, "with due deference to the judgment of others,

that in my opinion it is important to the well-being of society that the study of medicine by Christian women should be continued and extended. The difficulties that are said to attend their pursuing the necessary studies in the same schools with men may be obviated by judicious precautions, and these difficulties should not debar women from the profession of medicine. The prejudice that allows women to enter the profession of nursing and excludes them from the profession of medicine cannot be too strongly censured."

The annual reports for 1890 of our two special Eye and Ear Hospitals—the Presbyterian, and the Baltimore Eye, Ear and Throat Charity Hospitals, were published in January. In the former, which is much the larger, being supported with zeal and liberality by the large and wealthy Presbyterian denomination of this city, there were 9096 entries, with an average work-day attendance of 115; 1,517 operations were performed and 586 patients were treated in the wards averaging 9 days for each. In the other institution, now in its 9th year, 2,620 patients were treated; 971 of these were colored and 1,649 white; 1,632 were eye cases, 414 ear, and 599 throat cases; 226 operations were performed. The dispensary recorded 8,329 visits.

A course in hygiene is being conducted and will continue through the spring at the Johns Hopkins Hospital, under the direction of Drs. John S. Billings and Alex. C. Abbott, the latter assistant in bacteriology and hygiene; it consists of lectures and laboratory work, and embraces studies and investigations in the hygiene of atmosphere, water, ground, milk, meat, heating, ventilation, disinfection, building material and clothing. It is announced that Dr. Abbott has received and will accept a call to the hygienic laboratory of the University of Pennsylvania.

The Academy of Medicine of Baltimore is defunct. Instituted in May, 1877, by a number of the older physicians of the city, it began an unpopular career by requiring that candidates for membership should have been ten years in practice. Later it relaxed so far as to permit those excluded, to enter upon the presentation of an acceptable thesis. A few availed themselves of this privilege to become members, but the society never was vigorous, and ultimately perished for the want of that young and working element of which it had voluntarily deprived itself. There were those who thought that had it begun by requiring of all its candidates without regard to age, theses, the result would have been different.

At recent elections held in our several societies, the following were chosen presidents: Gynecological and Obstetrical, Dr. Henry M. Wilson; Medical Association, Dr. J. Edwin Michael; Medical and Surgical Society, Dr. David Street.

A change in the editorial management of the

Maryland Medical Journal places Prof. J. Edwin Michael in charge of that journal, whilst the retiring editor, Dr. Wm. B. Canfield, assumes charge of our new journal, the *Baltimore Medical and Surgical Record*. Dr. Michael is one of our best writers and speakers, and is energetic, courageous and talented. His appointment promises well for the future of the journal.

To the Alumni of the University of Maryland, scattered far and wide, it will be of interest to learn that the present class of the old school have adopted maroon and black as the University colors, and a yell—"Rah! Rah! Ree! U-ni-V of M.D. Rah!"

Although the Koch lymph has been used in our four principal hospitals, no results have been made known as far as I have seen except those at the Hopkins. Whilst the expressions of the Hopkins staff are reserved, they are decidedly favorable. More time is evidently required to know the true value of the method, and the cautious utterances of Dr. Osler and his associates cannot but elicit our commendation. Prof. Osler met with one case, where, although there were bacilli in the sputa, and other evidences of phthisis, there was no reaction after injections of 0.003 mg. of the fluid.

According to the figures of the Federal Census taken last June, Baltimore then had 434,439 inhabitants; the police census taken in November made it 455,427, the increase in ten years was 101,838 or 30.34 per cent.; about one fourth of this increase was derived from annexing two miles of territory on the north and west of the city. During the same period the per cent. of increase in the State at large was only 11.28. The city has been steadily gaining on the State ever since the first census in 1790; at that time, it had only 4.22 of the State's population, whereas in 1890 it had 41.73 per cent. E. F. C.

BOOK REVIEWS.

ILLINOIS STATE BOARD OF HEALTH. Seventh Report on Medical Education, Medical Colleges, and the Regulation of the Practice of Medicine in the United States and Canada, 1765-1891. Medical Education and the Regulation of the Practice in Foreign Countries. By JOHN H. RAUCH, M.D., Secretary. 1891.

For the first time in its history the Report on Medical Education, issued by the Illinois State Board of Health, embraces the medical institutions of the whole world. This is a feature that will be an assistance to medical boards that have to determine the value and validity of a medical diploma.

As regards medical education in the United

States, the Report shows the marked changes for the better that have taken place in the past ten years, and it is seen that more progress will be made within the next two years. Most of the changes for the better that have been made in this century have occurred since 1881, when the first number of this Report was published, and since 1882-83, when the schedule of minimum requirements of the Illinois State Board of Health went into effect. In 1882 only 45 colleges in the United States and Canada required educational qualifications for matriculation; now the number is 129. Of the 148 medical colleges 123 now teach hygiene and 119 teach medical jurisprudence. In 1882 these branches were taught in 52 and 61 colleges, respectively. In 1882-83 the average length of the lecture terms was 23.5 weeks; the average is now 26.3 weeks. There are now 111 colleges that have lecture terms of 6 months or more, while in 1882-83 the number was 42. A table shows the results of the examinations before the State Boards of Medical Examiners of Alabama, Minnesota, New Jersey, North Carolina, South Carolina and Virginia, since the dates of their organization. Another table shows the results of the Prussian State Examinations in 1890.

Special attention is called to the fact that in some of the largest universities in this country courses preliminary to the study of medicine are now offered—the University of Pennsylvania, Cornell, Yale, Princeton, Lake Forest and Northwestern Universities, Johns Hopkins and the University of Wisconsin, while Harvard has made arrangements by which those intending to study medicine can take a special A. B. course in three years. The course offered by the University of Wisconsin is fully outlined, as is the one that was proposed by the Medical Department of the University of Michigan, but was rejected by the joint faculties. The Report shows a marked increase in requirements as to preliminary education during the year 1890. It shows also that the movement for four years' study and three courses of lectures is an assured success, and a list is given of the colleges that have adopted or will soon adopt the requirements of longer terms of study.

Several State Boards, having authority similar to the Illinois Board, have already adopted the requirement in this respect, and those that have not already done so, will in a short time coöperate in the movement. The potency of this factor will be appreciated when it is considered that these boards directly control the recognition of diplomas in an area embracing about 41,000,000 people, and indirectly in almost the entire area of the United States; and that a number of them exercise jurisdiction in the new States and Territories.

It is suggested in the Report that, with four

years' study and three courses of lectures assured, the boards of medical examiners and the colleges should cooperate in establishing a system of registration of medical students before they enter college, in order that the requirement of one year of study outside a college may not be a mere form.

A correct *résumé* of the Medical Practice Acts in the different States and Territories is a valuable addition to the Report. Comprehensive tables show the progress made towards higher medical education in the past ten years, with the numbers of matriculates and graduates for each year, and the percentage of graduates to matriculates. These tables show the effect of the schedule of minimum requirements of the Illinois Board after the session of 1882-83. In 1882-83 the total number of medical students in the United States was 12,274, while in 1884-85 it was 10,987; and the 12,000 mark was not reached again until 1887-88. The percentage of graduates to matriculates in the United States has fallen from 35.8 in 1881-82 to 30.1 in 1890. The percentage in Canada has not reached 24 in ten years.

That portion of the Report devoted to institutions and regulations in foreign countries contains in full the requirements of the examining boards in Great Britain, with the names of all the medical schools and of all the hospitals in which instruction is given. The requirements as to preliminary education in foreign countries are given for purposes of comparison, as well as the requirements for graduation and for the license to practice. The course of study and the semesters in which the various subjects should be taken up, as advised in the German universities, as well as a description of the German method of examining for the license to practice, are given in full. In addition, the correct names and locations of foreign medical institutions are given.

A COMPEND OF DISEASES OF CHILDREN. Especially adapted for the use of medical students. By MARCUS P. HATFIELD, A.M., M.D., etc. With a colored plate. Philadelphia: P. Blakiston, Son & Co. 1890. Pp. 185. \$1.00. (Quiz-Compend No. 14.)

We have no hesitancy in saying that the neat little volume before us is a succinct presentation, in a pleasant form, of *many* of the diseases of children. To say that it is a *complete* compend would require the critic to ignore almost wholly the existence of such an important feature of the human economy as the respiratory system.

Of all the diseases of early life a very large number belong to either the digestive or respiratory tracts; yet, whereas upwards of forty pages are devoted to diseases of the digestive apparatus, it is impossible to find space given to respiratory affections—aside from two or three pages upon atelectasis pulmonum and asphyxia neonatorum. The author must certainly have a due apprecia-

tion of such diseases as catarrhal laryngitis, pseudo-membranous laryngitis, bronchitis, pneumonia, pleuritis, etc., and the importance of their intelligent treatment at the bedside of the child.

The subject of intestinal worms, also, remains untouched.

NECROLOGY.

Professor Charles T. Parkes.

Charles T. Parkes, Professor of Surgery in Rush Medical College, one of the leading and most popular surgeons in the United States, died at his home, No. 51 Lincoln avenue, Chicago, Ill., March 28, at 3:30 A.M. Death resulted from pneumonia produced by an attack of the "grip," the illness dating from Monday, March 16.

Dr. Parkes was born in Troy, N. Y., in 1847. He served during the war in an Illinois Volunteer Regiment, and was mustered out as Captain in 1865.

Entering upon the study of medicine he at once assumed a foremost position in his classes, and from 1868 until 1875 was Demonstrator of Anatomy in Rush Medical College. He was then advanced to the Chair of Anatomy, which professorship he held until his appointment to the Chair of Surgery in the same institution, made vacant by the death of Prof. Moses Gunn. His advancement in his profession was phenomenal, and this sudden termination to his brilliant career will bring grief to the hearts of all who knew him.

The family of Dr. Parkes is sojourning in Europe; his wife and only daughter being in Italy, and his only son in Paris, to whom the sad news has been cabled. His remains have been placed in a receiving vault to await their return. This signal loss to his city, to his State, and to the country will be more fully referred to when by the faculty of his college and by the various medical organizations, in which he rendered such conspicuous services, appropriate action shall have been taken.

ASSOCIATION NEWS.

American Medical Association.

The Forty-second Session of the American Medical Association will be held in Washington, D. C., on Tuesday, Wednesday, Thursday, and Friday, May 5th, 6th, 7th, and 8th, commencing on Tuesday at 11 o'clock, A. M.

Section of Oral and Dental Surgery.

The following is a list of Essayists (with subjects), who have promised to prepare papers for the Section of Oral and Dental Surgery:

Address of the Chairman of Section, Dr. Eugene S. Talbot.

"Adenoid Growth," Dr. W. H. Atkinson.

"Treatment of Fractures of the Maxilla," Dr. Wm. Carr.

"Genesis of Contour Fillings," Illustrated. Dr. Geo. S. Allan.

"The Teeth of Invertebrate Animals," Dr. A. H. Thompson.

"Some practical points on the care of Instruments," Dr. Wm. H. Potter.

"Rheumatic and Gouty Diathesis as Manifested in Diseases of the Parodontal Membrane," Dr. John S. Marshall.

"Dental Infirmary Patients,—The Use and Abuse of Dental Charity," Dr. Richard Grady.

"Growth of the Cementum," Dr. R. R. Andrews.

"Remarks on Incipient Necrosis and Caries," Dr. J. Williams.

"Choice of Therapeutic Filling Materials," Dr. W. A. Allport.

"Thorough Dentistry vs. Partial Dental Surgery," Dr. J. Y. Crawford.

"Pathological Conditions produced by Galvanic action between dissimilar Metals in the Mouth," Dr. George W. Whitefield.

Other members who desire to read papers before this Section, should as required by the By-Laws, forward the paper or its *title and length*, to the Chairman, Dr. Eugene S. Talbot, 125 State St., Chicago, Ill., one month before the meeting.

HENRY W. MORGAN, Sec'y.

Nashville, March 25, 1891.

Preliminary Announcement of Programme of the Section of Neurology and Medical Jurisprudence.

"Psychological Social Problems," by Daniel Clark, Toronto, Canada.

"Status Epilepticus," by Gros R. Trowbridge, and Chas. B. Mayberry, Danville, Pa.

"The Neuroses from a Demographic Point of View," by Irving C. Rosse, Washington, D. C.

"The Functional Degeneracy of the Brain," by J. T. Searcy, Tuscaloosa, Ala.

"Diagnosis of Traumatic Lesions in the Cerebro-Spinal Axis and the Detection of Malingering Referred to this Centre," by B. A. Watson, Jersey City, N. J.

"A Consideration of Traumatic Lesions of the Spine Resulting from Railroad and Other Injuries: Their Immediate and Remote Results. Etiology, Pathology and Diagnosis," by Thos. H. Manley, New York, N. Y.

General discussion of "The Traumatic Neuroses with Especial Reference to Railway Injuries," to be opened by R. Harvey Reed, Mansfield, Ohio.

"Rib-Fracture in Insane Hospitals in its Medico-Legal Aspects," by Jas. G. Kiernan, Chicago, Ill.

"Medico-Legal Investigation of Death by Violence in the State of Massachusetts," by Silas B. Presberry, Taunton, Mass.

"A Medico-Legal Study of Blood Corpuscles in Syphilis and Other Diseases," by Ephraim Cutter, New York, N. Y.

"On What Constitutes Reliable Evidence in Trials of Criminal Poisoning," by John Reese, Philadelphia, Pa.

"Hallucinations of the Sane," by David Inglis, Detroit, Mich.

"Personality as it Effects Inebriety," by T. L. Wright, Bellefontaine, O.

"Opium Inebriety, its Legal Recognition and Treatment," by W. S. Watson, Matteawan, N. Y.

"Ether Inebriety," by Norman Kerr, London, Eng.

"The Prevention of Opium Inebriety," by J. B. Mattison, Brooklyn, N. Y.

"The Treatment of Opium Neuroses," by Stephen Lett, Guelph, Canada.

T. D. CROTHERS, M.D., Chairman.
HAROLD N. MOYER, M.D., Sec'y.
434 W. Adams street, Chicago.

SPECIAL CORRESPONDENCE.

Shall The Journal be Removed to Washington?

ACTION OF THE NORTH CENTRAL OHIO MEDICAL SOCIETY.

The following preamble and resolution was unanimously adopted and ordered published in THE JOURNAL at the forty-first quarterly meeting of the North Central Ohio Medical Society, held at Mansfield, Ohio, March 27, 1891:

WHEREAS, An effort is being made to remove THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION from Chicago, Ill., to Washington, D. C.; and

WHEREAS, THE JOURNAL which was born in Cleveland, Ohio, has been so well nurtured in Chicago that it has grown from a dependent unsupported infant to an independent self-supporting adult, which commands the respect and support of the profession throughout the Continent, and now stands among the first of any of its colleagues in America; and

WHEREAS, It has accomplished all this in the short space of seven years through the judicious management and untiring energies of its Trustees, Supervising Editors and Business Manager.

THEREFORE, Be it resolved that it is the sense of the North Central Ohio Medical Society in convention assembled this 27th day of March, 1891, at Mansfield, Ohio, that it is against the best interest of THE JOURNAL and the Association to have it removed from Chicago to Washington, and hereby instruct our delegates to oppose such removal.

R. HARVEY REED, J. W. CRAIG, M. J. FINLEY, A. V. PATTERSON, J. HARVEY CRAIG, W. H. RACE, W. H. SYKES, A. H. MCCULLOUGH, R. D. SYKES, F. C. LARRIMORE, W. S. MECKLEN, W. M. MILLER, W. E. LOUGHRIDGE, Geo. MITCHELL, Josiah S. HEDGES

Very respectfully submitted.

R. HARVEY REED, Prest. J. S. HEDGES, Sec'y.

To the Editor:—I protest against using any more of the space of THE JOURNAL discussing its removal, and with S. E. Hampton, M.D., of Kentucky, move the previous question. Am willing that it should remain at Chicago, only make a good Journal of it. Am happy to note improvement. L. M. GATES, M.D.

Scranton, Pa., March 23, 1891.

To the Editor:—As many of the letters in THE JOURNAL opposed to its removal to Washington are from the West, I write, as originally from New England and living East, to express my opinion and firm belief that the best interests of THE JOURNAL will be served by keeping it in Chicago.

The fact that full delegations of the profession in and near Washington will be at the meeting to vote for removal should induce delegates of the North, South and West to attend the meeting and vote against removal, so that the small percentage of membership favoring removal may not out-vote the vast majority opposed to removal from the remoteness of one party and nearness of the other party to the place of meeting.

F. B. DAVISON, M.D.

Fleetville, Lackawanna Co., Pa.

To the Editor:—It is a poor plan to swap horses while crossing a stream. THE JOURNAL is successful and grows steadily more so, and I see no valid reason for making any change in its present location.

JOHN P. GRAY, M.D.

Utica, N. Y., March 28, 1891.

To the Editor:—Had I a dozen votes on the location of THE JOURNAL not one of them would be cast for Washington; it should, in my opinion, be published at some central point: Chicago, Cincinnati, or St. Louis; but if it is to go East, let it be to Philadelphia, New York, or Boston.

Washington is the place for many things of National importance;—a quiet place for legislators to meet—it is a National burying ground full of monuments; there can be found the remains of many men, things, and enterprises; in fact hundreds of clever, live men are buried there in the various departments yearly, but Washington is not the place for the headquarters of the American Medical Association or its organ. Keep the one on wheels, the other in Chicago. J. W. HOLDAY, M.D.

Burlington, Ia., March 28, 1891.

To the Editor:—It seems strange that the whole membership of the American Medical Association should be so aroused over the question of the removal of the home of THE JOURNAL, if it is to be such a gain as some would make it appear.

Is it possible that Washington City can furnish us so much better editorial material and the Association not find it out until it has been told to us by themselves or their allies in *intrigant*?

When a question of so much moment as the resigning of so important a journal to an ignominious death to furnish a stepping-stone for somebody to raise themselves into greater prominence is to be met, it seems as if the whole membership ought to be questioned, and each allowed himself to answer.

A selfish motive, cloaked as this was at birth, cannot expect to meet with any other answer from them against whom the scheme was laid, and *now an answer should be given that would henceforth doom such actions to infamous obloquy*. The suddenness and untimely hour of springing the subject does not show honesty of purpose, and since the question is being agitated, how few champions are showing in the list for the unseemly act, and when one does he is unkind enough to make charges of incompetency against the editorial management, and the manner in which the Trustees are conducting the publication. Men who stoop to vilify their compeers do not, at least, show a generous nature, into whose hands one would desire to place a trust of so much importance as the control of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

If there be not "method in their madness," why did they so secretly secure the promise of furtherance of their scheme by a member before he was promised the nomination to fill a vacancy on the Board of Trustees last spring? It is such Washingtonian acts that have so aroused the members in all parts of this great country to answer against the removal. This is not the work or wish, seemingly, of a North or South, an East or West, but that of a few with wild dreams of imaginary honor, who live to thrive on "such stuff as dreams are made of." Were they to be deprived of the National pap, and left to their own ability and natural resources, they would dwindle into less than nature had ordained them.

Men and their works do not become great because of the opportunities offered, but because of opportunities accepted and made use of.

Chicago may yet lead Washington in extensive libraries and institutions of learning, because of its inherent energy and push to the front. If there be any stored up energy in Washington otherwise than that which bubbles and seethes in the political caldron, would it not be well to take it to Chicago, where it can find a wholesome atmosphere to thrive upon and freedom of association of its kind? The home of THE JOURNAL undoubtedly was at first well chosen, at least it has proven well; and it is but fair to keep it where it has prospered so well.

A. M. VAIL, M.D.

Rock Rapids, Ia., March 25, 1891.

Editorial Opinions of the Medical Press.

In another column will appear the proceedings of a recent meeting of the Board of Trustees of the American Medical Association Journal at Washington. As will appear, the Board has announced as its belief, that Washington City is the proper place for the home of The Journal. The editor of the *Mirror*, as a member of the Board of Trustees, has favored and does favor, not only as a member of the Board, but as an individual, the removal of the Association Journal to Washington. He believes that the action of the Board in deferring the final decision until the meeting in May and inviting an expression of opinion from the profession at large upon the subject, was appropriate. A number of members of the Association in the West, near and dear friends of the writer, have expressed the thought that The Journal ought not to go East; that it was now in the West and that we ought to keep it here. Were the effort being made to remove The Journal to New York, Philadelphia, Boston, or any other commercial Eastern city, we believe that the argument would hold; that it would be removing it to the Eastern line and away from the centre. The same argument might be brought against its removal to any of the other cities of the West. As a matter of fact, Chicago is not a Western city. Chicago is, more properly speaking, a branch of New York City, although it is supposed to be a representative Western city, it is not at all so. Were geographical considerations to have weight, St. Louis would be more properly the centre. Unquestionably it is the hub of the Continental wheel, toward which all the spokes point.

It is the distributor of supplies to a greater territory than any other city in America. But in spite of these arguments, we are not in favor of the removal of The Journal to St. Louis; nor would we favor its removal to Cincinnati, Louisville, or any point South. In truth, any commercial city in America, suggested, would be a sectional suggestion. The removal of The Journal to Washington, however, the home of the National Government, is appropriate. A representative of the American medical profession, a National medical journal, should unquestionably be located in the Nation's Capital, the only unsectional point in America. We are strong in the conviction that this is not only the patriotic view to take of the question, but it is the view that is in the direction of the best good to the American Medical Association. A by-law, which was adopted some years ago by the Association, provided for every alternate meeting of the Association to be held in Washington City, looking toward Washington City as being eventually, in fact even now, the home of the National Association. If appropriate efforts were made, unquestionably a very large fund could be secured and a permanent building erected for the accommodation of the Association and its Journal in Washington. The various International Congresses are held the world over in the capitals of the various nations. The home of the *British Medical Journal* is in London; in fact, we are strong in the belief that all the arguments are in favor of the permanent home of the American Medical Association and its official organ, being located in the Capital of the Nation. If the time ever comes, that the Capital should be moved to a more central point, geographically speaking, then let the Association follow the Capital. In the meantime, we hope that there will be a full and free discussion in every medical journal of the United States. The Board of Trustees of The Journal have invited the freest discussion on the part of the members of the profession. The *Medical Mirror* will be glad to hear from those of the profession who are interested in the question.

In the meantime, we are on record as being in favor of the National Capital as the home of The Journal; but we are open to conviction, and shall remain in a receptive state of mind, ready for the suggestions and arguments of all friends of the Association.—*Medical Mirror*, Dec., 1890.

According to an official report of a meeting of the Board of Trustees of The Journal, held in Washington, D. C., Nov. 13th, 1890, three things were done:

1. The Board called upon the President of the United States.

2. It resolved that the home of The Journal should be in Washington, and that the Association should be so informed.

3. The Trustees recommend that the members of the Association, and the various State and local societies, contribute funds for the erection of a permanent building as an office, library, etc., of the American Medical Association.

Aside from some criticism of the Secretary's mode of keeping his book, this is all the Board report having done at this meeting; and yet a fair estimate of the actual expenses of the members in attendance will make it *cost not less than three hundred dollars*—probably four hundred would be nearer correct. Is the Association so rich that it can afford to pay its Trustees three or four hundred dollars to make a trip to Washington, in order that the Board may visit the President of the United States, and announce gravely to the Association that it should permanently locate The Journal in Washington, and call upon individuals and societies in the profession for funds to erect a building?

The members of the Association would like to learn why the Board of Trustees, or any portion of it, deemed it fitting to gravely announce its opinion upon the subject or subjects, and why Washington is better than Chicago? This is a question for the Trustees to answer! Further, what reason is there for making this question prominent just now? We desire to vote and act intelligently upon this question, hence seek for information.

We do know that several years ago the Trustees carefully secured bids from publishing houses, printers, etc., in all principal cities of the United States, with the uniform result of ascertaining that Washington was the most expensive, and Chicago the cheapest, place of publication. Have the Trustees made full and complete investigations, with the result of finding a cheaper place of publication than Chicago? If so they should have announced the fact, and the grounds upon which it rested.

Do the Trustees desire to move The Journal to Washington because hitherto every medical journal issued there came to an untimely end? Can it be that they desire to plant The Journal in a spot hitherto noted for its failures in medical journalism? Have they a hope that under the special influence for which Washington is noted, The Journal of the Association will die an easy and painless death? Or is it because the Trustees have a grudge against eastern medical journals in general, and the medical weeklies in particular, that they desire to transfer The Journal to an eastern locality. Naturally it would seem as if the strip of country along the Atlantic coast had medical journals in abundance, and that the removal thither of another would act more or less disadvantageously. On this view of the fact, it would appear that the Trustees of The Journal either resolved thoughtlessly, or were acting in disregard of the interests of other journals.

Can a better or more reliable business manager be secured in Washington? Can better or more effective editorial work be secured? In short, is there a single reason for fixing The Journal permanently in Washington? We have not heard of a single reason that counts in favor of The Journal or of the Association. We are informed that such location is desirable because Washington is the Nation's Capital; but the publication of The Journal is a business to be conducted upon business principles, for the attainment of business ends. If there are good business reasons for locating The Journal in Washington, we have yet to learn of them. The fact that Washington is the Capital affords the strongest of reasons why such a business as the conduct of a great medical journal should not be located there; a great commercial centre is the

place for a business that is National in its scope, and Washington is not such a centre. More anon.

N. B.—If we hear any reasons for removing The Journal to Washington, we shall lay them before our readers, that all may be prepared to vote intelligently upon the question.—*The American Lancet*, Jan., 1891.

The minutes of the Board of Trustees of The Journal, published in a late edition, show that an attempt has been made to move the plant to Washington. There is some question as to the advisability of such a proceeding at this time, when in the course of the next two years so many medical men from all over the world will visit Chicago, the place where The Journal was born and nurtured. Admitting that it is in some respects a Chicago journal, the question arises as to whether it would be any better, or have a greater influence or larger circulation if it were a Washington journal instead of what it is at the present time? With all due respect to Dr. Hamilton, it is suggested that his official position should prevent him from entering into any political schemes by which he will reward his friends and punish his enemies.

The time has not yet arrived when the members of the Association can afford to trust the welfare of The Journal in the hands of those who are not directly and personally interested in its progress and permanent success. Attempts have been previously made to corral the members of the Board, with a view to manage the paper to the personal advantage of those who desired to "run it for the money there was in it," but, fortunately, all such efforts have heretofore failed, and it is hoped a like fate will attend this last attempt, although it may have been considered with the best intentions. Let it be understood, once and for all time, that The Journal cannot be bought, merged or hypothecated.—*Philadelphia Medical Summary*, Jan., 1891.

The question of the removal of The Journal from Chicago to Washington City is being agitated. A meeting of the Board of Trustees has already been held to that effect. The final decision has been deferred until the meeting in May, when an expression of opinion from the profession at large upon the subject will be had. We think it folly to ask its removal to Washington, simply because it is the home of the National Government, in order that it may be designated a National Medical Journal. Washington is not, never has been and probably never will be a medical centre, and neither its location nor railroad facilities recommend it.—*Kansas Medical Journal*, Jan., 1891.

Shall the A. M. A. Journal go to Washington? This is the question which the Association will be called upon to answer at its next meeting. The Board of Trustees, at a recent session in Washington, adopted a resolution favoring the change, but not a single "Whereas" precedes the "Resolution." What are the reasons for wanting the change made? Surely they exist in the minds of the Trustees, and as officers of the Association having at heart the best interest of this organization, those reasons should be made public. Can The Journal be published cheaper in Washington? That can hardly be, for Chicago is a great publishing centre. Are the mailing facilities at Washington better? Mr. Wanamaker would hardly admit that they are. Can it be better edited at Washington? That's a "sure enough" question. The Association will be very certain to know something about a prospective editor before it votes upon this matter. In the far Eastern country the Islam prophet of old failed in an attempt to make the mountains skip at his command as kids at play, but perhaps "a greater than he is here." It does look as though the mountain were seriously contemplating a journey in a Pullman palace car to a Mahomet who has bid it come. In all soberness,

Messrs. Trustees, let the Association know why your assembled wisdom deems it best to transfer The Journal to Washington. Let it stay where it now is unless certainly shown that the interests of both the Association and its Journal will be conserved by its removal.—*Medical Herald*, Feb., 1891.

A great controversy is now being carried on regarding the proposed removal of The Journal from its home in Chicago to Washington City. The control of The Journal is in the hands of a Board of Trustees, which has recommended that the change be made. The question will come up at the next meeting in Washington, and there will be a warm discussion, and possibly indefinite results.

The time for an opinion upon this proposition is not arrived, for we are sure that the best arguments for the removal have not as yet been advanced. We fear that the action of the Trustees in referring the matter to the Association is wrong, and will result in harm. The Board was given full power to act; by its act The Journal was located in Chicago, and by its authority it could remain or be removed.

As it is now, there is a pretty war on hand, and it will grow fiercer and hotter as the time for the meeting draws nigh. Even if a conclusion be reached at the next meeting, it may be undone at any succeeding one. We hope a motion will prevail to refer the question back to the Trustees. They are abundantly able to settle the matter—in fact, are elected to carry just such responsibility. We will have something to say about the arguments for and against removal further along.—*St. Louis Clinique*, Feb., 1891.

At the last meeting of the Trustees of The Journal of the American Medical Association, it was resolved to move The Journal from Chicago to Washington. By subsequent resolution, however, it was determined to leave the matter open until a vote could be had by the members at the May meeting. The question is therefore a proper one for agitation and it is well enough to consider the pros and cons relative to a matter of so much importance to so large a number of the medical profession.

The Journal when established was located in Chicago, largely because Chicago influence was dominant in the Association, but chiefly because it was a central point from which proofs could be readily sent to writers and as readily returned. This convenience has been experienced by contributors to The Journal, the vast majority of whom reside in the great interior valley of our broad country. Since the location of the official organ of the Association at Chicago, type and other fixtures have been purchased, and the periodical under conservative management has become one of the most influential in the country. But now right on the heels of this success comes an effort to take The Journal from its central and convenient location and publish it in a provincial city on one side of the continent.

The question is at once asked why? Is it because there are no longer printing presses in Chicago? Is it because the paper market in that city has become exhausted? Is it because the mailing facilities in that metropolis are inadequate? Is it because there are no men of brains to be found either in that great and growing medical center, or who can be induced to take up their residence there to assume editorial charge of one of the leading medical journals of the country? These are the only reasons that are entitled to consideration relative to changing the location of a great journal and yet a knowledge of the facts in the present instance condemn them as absurd to the verge of idiocy.

The only reason so far given by the promoters of the move is that Washington is the Capital of the country. Well what of it? Are there better presses, more paper,

faster mailing facilities or more brilliant intellects in Washington than in Chicago? The Capital is merely a political center and as such is inimical to the highest development of science or literature. We do not want the politics of the Capital engrafted upon the journalistic interests of the American Medical Association.

Gentlemen of the West and South, be at Washington on May the 5th and vote upon this question.—*Cincinnati Medical Journal*, Feb. 15, 1891.

MISCELLANY.

THE BIG FOUR AND THE ANNUAL MEETING OF THE ASSOCIATION.—To members of the American Medical Association who contemplate attending the annual Meeting at Washington, D. C., May 5th to 8th, a few words in regard to the best means of reaching Washington will no doubt prove acceptable. The recognized line from Chicago is the Popular Big Four Route in connection with the Scenic Chesapeake & Ohio Ry., from Cincinnati running via White Sulphur Springs, through the beautiful mountain regions of the Virginias, over its own tracks into the City of Washington.

Passengers via this popular line have the choice of two elegant trains, starting from Lake Street Depot, Chicago,—the morning train equipped with elegant parlor cars, cafe dining car and luxurious coaches, makes connection at Cincinnati with the Famous "Fast Flying Virginian" via the C. & O. Route, assuring passengers of first class service, including Dining Cars, for the entire trip. The evening train from Chicago is equipped with private compartment buffet sleeping car, standard Wagner palace sleeping car and elegant reclining chair car and makes connection with the "Washington Fast Line" via the Chesapeake & Ohio Ry., affording a day-light ride through the beautiful Ohio Valley, and across the scenic Blue Ridge Mountains into the Capital.

These trains are vested throughout, provided with an unequalled dining car service and afford every comfort and convenience of modern railroading. For tickets and full information call on or address J. C. Tucker, General Northern Agent 121 Randolph St., Chicago, Ill., D. B. Martin General Pass. Agent Big Four Route Cincinnati, O.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from March 21, 1891, to March 27, 1891.

Major Henry R. Tilton, Surgeon U. S. A., is hereby granted leave of absence for one month, on surgeon's certificate of disability. Par. 5, S. O. 56, Hldrs. Div. Atlantic, March 21, 1891.

Major Passmore Middleton, Surgeon, is relieved from duty at St. Francis Bks., Fla., and will proceed to Newport Bks., Ky., and await further orders. The travel enjoined is necessary for the public service. By direction of the Acting Secretary of War. Par. 8, S. O. 62, A. G. O., Washington, March 19, 1891.

Major John H. Barthol, surgeon, now on duty at Plattsburgh Bks., N. Y., will proceed to Fort Wayne, Mich., and report in person to the commanding officer of that post for temporary duty. By direction of the Acting Secretary of War. Par. 7, S. O. 64, A. G. O., Washington, March 2, 1891.

Capt. Henry Johnson, Medical Storekeeper, retirement from active service this date, under the provisions of the Act of Congress approved June 10, 1882, is announced. By direction of the Acting Secretary of War. Par. 8, S. O. 66, A. G. O., Hldrs. of the Army, Washington, March 21, 1891.

Capt. Robert J. Gibson, Asst. Surgeon, leave of absence granted in S. O. 22, A. G. O., October 3, 1890, from this office, is extended one month. By direction of the Acting Secretary of War. Par. 10, S. O. 65, A. G. O., Washington, March 23, 1891.

First Lieut. Eugene L. Swain, Asst. surgeon, now on duty at Ft. Thomas, Ariz., will report by letter to the commanding officer, Ft. Grant, Ariz., for duty at that station or Ft. Thomas, Ariz., as the commanding officer may direct. By direction of the Acting Secretary of War. Par. 7, S. O. 66, A. G. O., Washington, March 21, 1891.

Lieut. Col. Charles R. Greenleaf, Asst. Medical Purveyor, will proceed to New York City on public business, and thence to Boston, Mass., to represent the Army Medical Department at the American Association for Physical Education, and upon the completion of the duties contemplated, will return to his station in this city. By direction of the Acting Secretary of War. Par. 3, S. O. 67, A. G. O., Washington, March 25, 1891.

ADDRESSES.

THE RELATION OF BACTERIA TO
PRACTICAL SURGERY.

*The Address in Surgery of the Medical Society of the State of
Pennsylvania, Pittsburgh, June 11, 1891.*

BY JOHN B. ROBERTS, M.D.,

PROFESSOR OF SURGERY IN THE WOMAN'S MEDICAL COLLEGE OF
PENNSYLVANIA, PROFESSOR OF ANATOMY AND SURGERY
IN THE PHILADELPHIA POLYCLINIC.

The revolution which has occurred in practical surgery since the discovery of the relation of microorganisms to the complications occurring in wounds has caused me to take up this subject for discussion. Although many of my hearers are familiar with the germ theory of disease, it is possible that it may interest some to have put before them, in a short address, a few points in bacteriology, which are of value to the practical surgeon.

It must be remembered that groups of symptoms which were formerly classed under the heads of "inflammatory fever," "symptomatic fever," "traumatic fever," "hectic fever," and similar terms, varying in name with the surgeon using them, or with the location of the disease, are now known to be due to the invasion of the wound by microscopic plants. These bacteria, after entering the blood current at the wound, multiply with such prodigious rapidity that the whole system gives evidence of their existence. Suppuration of wounds is undoubtedly due to these organisms, as is tubercular disease, whether of a surgical or medical character. Tetanus, erysipelas and many other surgical conditions have been almost proved to be the result of infection by similar microscopic plants, which, though acting in the same way, have various forms and life-histories.

A distinction must be made between the "yeast plants," one of which produces thrush, and the "mould plants," the existence of which as parasites in the skin gives rise to certain cutaneous diseases. These two classes of vegetable parasites are foreign to the present topic, which is surgery; and I shall, therefore, confine my remarks to that group of vegetable parasites to which the term bacteria has been given. These are the microorganisms whose actions and methods of growth particularly concern the surgeon. The individual

plants are so minute that it takes in the neighborhood of ten or fifteen hundred of them grouped together to cover a spot as large as the full stop or period used in punctuating an ordinary newspaper. This rough estimate applies to the globular or egg-shaped bacteria to which is given the name "coccus" (plural cocci). The cane, or rod-shaped bacteria are rather larger plants. Fifteen hundred of these placed end to end would reach across the head of a pin. Because of the resemblance of these latter to a walking stick they have been termed bacillus (plural bacilli).

The bacteria most interesting to the surgeon belong to the cocci and the bacilli. There are other forms which bacteriologists have dubbed with similar descriptive names, but they are more interesting to the physician than to the surgeon. Many microorganisms, whether cocci, bacilli, or of other shapes, are harmless; hence they are called non-pathogenic, to distinguish them from the disease-producing, or pathogenic germs.

As many trees have the same shape and a similar method of growing, but bear different fruit;—in the one case edible, and in the other poisonous—so, too, bacteria may look alike to the microscopist's eye, and grow much in the same way, but one will cause no disease, while the other will produce serious disease, such, perhaps, as tuberculosis of the lungs or brain.

Many scores of bacteria have been, by patient study, differentiated from their fellows and given distinctive names. Their nomenclature corresponds in classification and arrangement with the nomenclature adopted in different departments of botany. Thus, we have the pus-causing chain coccus (streptococcus pyogenes), so called because it is globular in shape; because it grows with the individual plants attached to each other, or arranged in a row like a chain of beads upon a string; and because it produces pus. In a similar way we have the pus-causing grape-coccus of a golden color (staphylococcus pyogenes aureus). It produces pus, grows with the individual plants arranged somewhat after the manner of a bunch of grapes, and when millions of them are collected together the mass has a golden yellow hue. Again, we have the bacillus tuberculosis; the rod-shaped plant which is known to cause tuberculosis of the lungs, joints, brain, etc.

It is hardly astonishing that these fruitful sources of disease have so long remained undetected, when their microscopic size is borne in mind. That some of them do cause disease is indisputable, since bacteriologists have, by their watchful and careful methods, separated a single plant from its surroundings and congeners, planted it free from all contamination and observed it produce an infinitesimal brood of its own kind. Animals and patients inoculated with the plants thus cultivated have rapidly become subjects of the special disease which the particular plant was supposed to produce.

The difficulty of such investigations becomes apparent when it is remembered that under the microscope many of these forms of vegetable life are identical in appearance, and it is only by observing their growth, when in proper soil, that they can be distinguished from each other. In certain cases it is quite difficult to distinguish them by their physical appearances produced during their growth. In such instances it is only after an animal has been inoculated with them that the individual parasite can be accurately recognized and called by name. It is known by the results it is capable of producing.

The various forms of bacteria are recognized, as I have said, by their method of growth, and by their shape. Another means of recognition is their individual peculiarity of taking certain dyes so that special plants can be recognized, under the microscope, by the color given to them, which they refuse to give up when treated with chemical substances which remove the stains from, or bleach, all the other tissues which at first have been similarly stained.

The similarity between bacteria and the ordinary plants with which florists are familiar is indeed remarkable. Bacteria grow in animal and other albuminous fluids, as a soil, but it is just as essential for them to have a suitable soil as it is for the corn or wheat that the farmer plants in his field. By altering the character of the albuminous fluid in which the microorganism finds its subsistence, these small plants can be given a vigorous growth or may be actually starved to death. The farmer knows that it is impossible for him to grow the same crop year after year in the same field, and he is, therefore, compelled to rotate his crops. So it is with these microscopic plants which we are considering. After a time the culture fluid or soil becomes so exhausted of its needed constituents by the immense number of plants living in it that it is unfit for their life and development. Then this particular plant will no longer thrive, but some other form of bacterium may find in it the properties required for functional activity, and grow vigorously. It is probable that exhaustion or absence of proper soil is an important agent in protecting man from sickness due to infection from bacteria. The ever

present bacteria often gains access to man's blood through external wounds, or through the lungs and digestive tracts; but unless a soil suited for their development is found in his fluids, the plants will not grow. If they do not grow and increase in numbers they can do little harm.

Again, there are certain bacteria which are so antagonistic to each other that it is impossible to make them grow in company, or to co-exist in the blood of the same individual. For example, an animal inoculated with erysipelas germs cannot be successfully inoculated immediately afterward with the germs of malignant pustule. Such antagonism is illustrated by the impossibility of having a good crop of grain in a field overrun with daisies. On the other hand, however, there are some microorganisms which flourish luxuriantly when planted together in the same fluid, somewhat after the manner of pumpkins and Indian corn growing between the same fence rails. Others seem unwilling to grow alone, and only flourish when planted along with some other germs. It is very evident, therefore, that bacteriology is a branch of botany, and that Nature shows the same tendencies in these minute plants as it does in the larger vegetable world visible to our unaided eyes.

As the horticulturist is able to alter the character of his plants by changing the circumstances under which they live, so can the bacteriologist change the vital processes and activities of bacteria by chemical and other manipulations of the culture substances in which these organisms grow. The power of bacteria to cause pathological changes thus may be weakened and attenuated; in other words, their functional power for evil is taken from them by alterations in the soil. The pathogenic, or disease-producing power, may be increased by similar, though not identical, alterations. The rapidity of their multiplication may be accelerated, or they may be compelled to lie dormant and inactive for a time; and on the other hand, by exhausting the constituents of the soil upon which they depend for life, they may be killed.

It is a most curious fact also that it is possible, by selecting and cultivating only the lighter colored specimens of a certain purple bacterium, for the bacteriologist to finally obtain a plant which is nearly white, but which has the essential characteristics of the original purple fungus. In this we see the same power which the florist has to alter the color of the petals of his flowers by various methods of selective breeding.

The destruction of bacteria by means of heat and antiseptics is the essence of modern surgery. It is, then, by preventing access of these parasitic plants to the human organism (aseptic surgery), or the destruction of them by chemical agents and heat (antiseptic surgery), that we are enabled to invade, by operative attacks, regions of the body which a few years ago were sacred.

When the disease-producing bacteria gain access to the tissues and blood of human and other animals by means of wounds, or through an inflamed pulmonary or alimentary mucous membrane, they produce pathological effects provided there is not sufficient resistance and health power in the animal's tissues to successfully antagonize the deleterious influence of the invading parasitic fungus. It is the rapid multiplication of the germs, which furnishes a continuous irritation, that enables them to have such a disastrous effect upon the tissues of the animal. If the tissues had only the original dose of microbes to deal with, the warfare between health and disease would be less uncertain in outcome. Victory would usually be on the side of the tissues and health.

The immediate cause of the pathogenic influence is probably the chemical excretions which are given out by these microscopic germs. All plants and animals require a certain number of substances to be taken into their organisms for preservation of their vital activities. After these substances have been utilized there occurs an excretion of other chemical products. It is probably the excretions from the many millions of bacteria circulating in the blood which give rise to the disease characteristic of the fungus with which the animal has been infected. The condition called *sapremia*, or *septic intoxication*, for example, is undoubtedly due to the entrance of the excretory products (*ptomaines*) of putrefaction-bacteria into the circulation. This can be proved by injecting into an animal a small portion of these products obtained from cultures of the germs of putrefaction. Characteristic symptoms will at once be exhibited.

Septicæmia is a similar condition due to the presence of the putrefactive organisms themselves, and hence of their products or *ptomaines* also in the blood. The rapidity of their multiplication in this albuminous soil, and the great amount of excretion from the numerous fungi, makes the condition more serious than *sapremia*. Clinically, the two conditions occur together.

The rapidity with which symptoms may arise after inoculation of small wounds with a very few germs will be apparent when it is stated that one parasitic plant of this kind may, by its rapidity of multiplication, give rise to fifteen or sixteen million individuals within twenty-four hours. The enormous increase which takes place within three or four days is almost incalculable. It has been estimated that a certain bacillus only about 1-1000 of an inch in length could, under favorable conditions, develop a brood of progeny in less than four days which would make a mass of fungi sufficient to fill all the oceans of the world if they all had a depth of one mile.

Bacteria are present everywhere. They exist in the water, earth, air, and within our respira-

tory and digestive tracts. Our skin is covered with millions of them, as is every article about us. They can circulate in the lymph and blood, and reach every tissue and part of our organisms by passing through the walls of the capillaries. Fortunately, they require certain conditions of temperature, moisture, air and organic food for existence, and for the preservation of their vital activities.

If their surroundings are too hot, too cold, or too dry, or if they are not supplied with a proper quantity and quality of food from the soil in which they are living, the bacterium becomes inactive, until the surrounding circumstances change, or die absolutely. The spores which finally become full fledged bacteria, are able to stand a more unfavorable environment than the adult bacteria. Many spores and adults, however, perish. Each kind of bacterium requires its own special environment to permit it to grow and flourish. The frequency with which an unfavorable combination of circumstances occurs limits greatly the disease-producing power of the pathogenic bacteria.

Many bacteria, moreover, are harmless and do not produce disease even when present in the blood and tissues. Besides this the white blood cells are perpetually waging war against the bacteria in our bodies. They take the bacteria into their interiors and render them harmless by eating them up, so to speak; and they crowd together and form a wall of white blood cells around the place where the bacteria entered the tissues, thus forming a barrier to cut off the blood supply to the germs and perhaps to prevent them from entering the general blood current.

The war between the white blood cells and bacteria is a bitter one. Many bacteria are killed; but, on the other hand, the life of many blood cells is sacrificed by the bacteria poisoning them with *ptomaines*. The tissue cells, if healthy, offer great resistance to the attacks of the army of bacteria. Hence, if the white cells are vigorous and abundant at the site of the battle, defeat may come to the bacteria, and the patient suffers nothing from the attempt of these vegetable parasites to harm him. If, on the other hand, the tissues have a low resistive power, because of the general debility of the patient, or of a local debility of the tissues themselves, and the white cells be weakened and not abundant, the bacteria will gain the victory, get access to the general blood current and invade every portion of the animal's body. Thus, a general, or a local, disease, will be caused; varying with the species of bacteria with which the patient has been infected, and the degree of resistance on the part of the tissues.

From what has been stated, it must be evident that the bacterial origin of disease depends upon the presence of a disease-producing fungus and a diminution of the normal or healthy tissue-re-

sistance to bacterial invasion. If there is no fungus present, the disease caused by such fungus cannot develop. If the fungus be present, and the normal or health tissue-resistance be *undiminished*, it is probable that disease will not occur. As soon, however, as over-work, injury of a mechanical kind, or any other cause diminishes the local or the general resistance of the tissues and individual, the bacteria have the upper hand, and are able to produce their malign effect.

Many conditions favor the bacterial attack. The patient's tissues may have an inherited peculiarity, which renders it easy for the bacteria to find a good soil for development; an old injury or inflammation may render the tissues less resistant than usual; the point at which inoculation has occurred may have certain anatomical peculiarities which make it a good place in which bacteria may multiply; the blood may have undergone certain chemical changes which render it better soil than usual for the rapid growth of these parasitic plants.

The number of bacteria originally present makes a difference also. It is readily understood that the tissues and white blood cells would find it more difficult to repel the invasion of an army of a million microbes, than the attack of a squad of ten similar fungi. I have said that the experimenter can weaken and augment the virulence of bacteria by manipulating their surroundings in the laboratory. It is probable that such a change occurs in nature. If so, some bacteria are more virulent than others of the same species; some less virulent. A few, of the less virulent disposition, would be more readily killed by the white cells and tissues than would a larger number of more virulent ones. At other times the danger from microbic infection is greater because there are two species introduced at the same time; and these two multiply more vigorously when together than when separated. They are, in fact, two allied hosts trying to destroy the blood cells and tissues. This occurs, for instance, when the bacteria of putrefaction and the bacteria of suppuration are introduced into the tissues at the same time. The former causes sapræmia and septicæmia, the latter cause suppuration. The bacteria of tuberculosis are said to act more viciously if accompanied by the bacteria of putrefaction. Osteomyelitis is of greater severity, it is believed, if due to a mixed infection with both the white and the golden grape-coccus of suppuration.

I have previously mentioned that the bacteria of malignant pustule are powerless to do harm when the germs of erysipelas are present in the tissues and blood. This is an example of the way in which one species of bacteria may actually aid the white cells, or leucocytes, and the tissues in repelling an invasion of disease-producing microbes.

Having occupied a portion of the time allotted to me in giving a crude and hurried account of the characteristics of bacteria, let me discuss the relations of bacteria to the diseases most frequently met with by the surgeon.

Mechanical irritations produce a very temporary and slight inflammation, which rapidly subsides; because of the tendency of nature to restore the parts to health. Even severe injuries, therefore, will soon become healed and cured, if no germs enter the wound.

Suppuration of operative and accidental wounds was, until recently, supposed to be essential. We now know, however, that wounds will not suppurate if kept perfectly free from one of the dozen forms of bacteria that are known to give rise to the formation of pus.

The doctrine of present surgical pathology is that suppuration will not take place, if pus-forming bacteria are kept out of the wound, which will then heal by first intention without inflammation and without "inflammatory" fever.

In making this statement I am not unaware that there is a certain amount of fever following various severe wounds within twenty-four hours, even when no suppuration occurs. This wound-fever, however, is transitory, not high, and entirely different from the prolonged condition of high temperature formerly observed nearly always after operations and injuries. The occurrence of this inflammatory, traumatic, surgical, or symptomatic fever, as it was formerly called, means that the patient has been subjected to the poisonous influence of putrefactive or suppurative germs.

We now know why it is that certain cases of suppuration are not circumscribed but diffused, so that the pus dissects up the fascias and muscles and destroys with great rapidity the cellular tissue. This form of suppuration is due to a particular form of bacteria called the pus forming "chain-coccus." Circumscribed abscesses, however, are due to one or more of the other pus-causing microorganisms.

How much more intelligent is this explanation than the old one that diffuse abscesses depended upon some curious characteristic of the patient. It is a satisfaction to know that the two forms of abscess differ because they are the result of inoculation with different germs. It is practically a fact that wherever there is found a diffuse abscess there will be discovered the streptococcus pyogenes, which is the name of the chain-coccus above mentioned.

So also is it easy now to understand the formation of what the old surgeons called "cold abscesses," and to account for the difference in appearance of its puriform secretion from the pus of acute abscess. Careful search in the fluid coming from such cold abscesses reveals the presence of the bacillus of tuberculosis and proves that a

cold abscess is not a true abscess, but a local lesion of tubercular infection. Easy is it now to understand the similarity between the "cold abscess" of the cervical region and the "cold abscess" of the lung in a phthisical patient. Both of them are, in fact, simply the result of invasion of the tissues with the ubiquitous tubercle bacillus; and are not due to pus-forming bacteria.

Formerly it was common to speak of the scrofulous diathesis, and attempts were made to describe the characteristic appearance of the skin and hair pertaining to persons supposed to be of scrofulous tendencies. The attempt was unsuccessful and unsatisfactory. The reason is now clear because it is known that the brunette or blonde, old or young, may become infected with the tubercle bacillus. Since the condition depends upon whether one or other becomes infected with the ever present bacillus of tubercle, it is evident that there can be no distinctive diathesis.

It is more than probable that the cutaneous disease so long described as lupus vulgaris is simply a tubercular condition of the skin, and not a special disease of unknown causation.

The metastatic abscesses of pyæmia are clearly explained when the surgeon remembers that they are simply due to a softened blood clot, containing pus-forming germs, being carried through the circulation and lodged in some of the small capillaries.

A patient suffering with numerous boils upon his skin has often been a puzzle to his physician, who has in vain attempted to find some cause for the trouble in his general health alone. Had he known that every boil owed its origin to pus bacteria which had infected a sweat gland or hair follicle, the treatment would probably have been more efficacious. The suppuration is due to pus-germs, either lodged upon the surface of the skin from the exterior, or deposited from the current of blood by which they have been carried to the spot.

I have not taken time to go into a discussion of the methods by which the relationship of microorganisms to surgical affections has been established; but the absolute necessity for every surgeon to be fully alive to the inestimable value of aseptic and antiseptic surgery had led me to make the foregoing statements as a sort of résumé of the relation of the germ theory of disease to surgical practice. It is clearly the duty of every man who attempts to practice surgery to prevent, by every means in his power, the access of germs, whether of suppuration, putrefaction, erysipelas, tubercle, tetanus or any other disease to the wounds or body of a patient. This as we all know, can be done by absolute bacteriological cleanliness. It is best, however, not to rely solely upon absolute cleanliness, which is almost unattainable; but to secure further protection by the use of antiseptic solutions. I am fully of the opin-

ion that chemical antiseptics would be needless, if absolute freedom from germs was easily obtained. When I know that even such an enthusiast as I, myself, is continually liable to forget or neglect some step in this direction, I feel that the additional security of chemical antiseptics is of great value. It is difficult to convince the majority of physicians, and even ourselves, that to touch during an operation a finger to a door knob, to an assistant's clothing, or to one's own body may be to vitiate the entire operation by introducing one or two microbic germs into the wound.

An illustration of how carefully the various steps of an operation should be guarded is afforded by the appended rules, which I have adopted at the Woman's Hospital of Philadelphia for the guidance of assistants and nurses. If such rules were taught every medical student and every physician entering practice as earnestly as the paragraphs of the catechism are taught the Sunday School pupil (and they certainly ought to be so taught) the occurrence of suppurative, hectic fever, septicæmia, pyæmia and surgical erysipelas would be practically unknown. Death then would seldom occur after surgical operations except from hæmorrhage, shock or exhaustion.

With this feeble plea, Mr. President and Members of the Society, I hope to create a realization of the necessity for knowledge and interest in the direction of bacteriology, for this is the foundation of Modern Surgery. There is, unfortunately, a good deal of abdominal work done under the name of antiseptic and aseptic surgery, because the simplest facts of bacteriology are unknown to the operator. I have taken the liberty of bringing here a number of culture tubes containing beautiful specimens of some of the more common and interesting bacteria. The slimy masses seen on the surface of the jelly, contained in the tubes, are many millions of individual plants, which have aggregated themselves in various forms, as they have been developed as the progeny of the parent cells planted in the jelly as a nutrient medium or soil.

RULES TO BE OBSERVED IN OPERATIONS IN DR. ROBERTS' SURGICAL CLINIC OF THE WOMAN'S HOSPITAL OF PHILADELPHIA.

After wounds or operations, high temperature usually, and suppuration always, is due to blood poisoning, which is caused by infection with vegetable parasites called bacteria. These parasites ordinarily gain access to the wound from the skin of the patient, the finger nails or hand of the operator or his assistants, the ligatures, sutures or dressings.

Suppuration and high temperature should not occur after operation wounds, if suppuration has not existed previously. Bacteria exists almost everywhere as invisible particles in the dust; hence, everything that touches or comes into even momentary contact with the wound must be germ-free; technically called "sterile." A sterilized condition of the operator, the assistant, the wound, instruments, etc., is obtained by removing all bacteria by

means of absolute surgical cleanliness (asepsis,) and by the use of those chemical agents which destroy the bacteria not removed by cleanliness itself (antisepsis). Surgical cleanliness differs from the housewife's idea of cleanliness in that its details seem frivolous, because it aims at the removal of microscopic particles. Stains such as housewives abhor, if germ-free, are not objected to in surgery. The hands and arms, and especially the finger nails of the surgeon and assistants and nurses, should be well scrubbed with hot water and soap by means of a nail brush immediately before the operation. The patient's body about the site of the operation should be similarly scrubbed with a brush and cleanly shaven. Subsequently the hands of the operator, assistants and nurses, and the field of operation, should be immersed in, or thoroughly washed with, corrosive sublimate solution (1 1000, or 1 2000). Finger rings, bracelets, bangles, cuffs worn by the surgeon, assistants or nurses, must be removed before the cleansing is begun, and the clothing covered by a clean white apron large enough to extend from neck to ankles and provided with sleeves.

The instruments should be similarly scrubbed with hot water and soap and all particles of blood and pus from any previous operation removed from the joints. After this they should be immersed for at least fifteen minutes in a solution of betanaphthol (1-2500), which must be sufficiently deep to cover every portion of the instruments. After cleansing the instruments with soap and water, baking in a temperature a little above the boiling point is the best sterilizer. During the operation the sterilized instruments should be kept in a betanaphthol solution and returned to it when the operator is not using them.

Sponges should be kept in a betanaphthol solution (or a corrosive sublimate solution) during the operation. After the blood from the wound has been sponged away, they should be put in another basin containing an antiseptic solution and must be thoroughly cleansed and sterilized anew before being used again. The antiseptic sutures and ligatures should be similarly soaked in betanaphthol solution during the progress of the operation.

No one should touch the wound but the operator and his first assistant. No one should touch the sponges but the operator, his first assistant, and the nurse having charge of them. No one should touch the already prepared ligatures or instruments except the surgeon and his first and second assistant. None but those assigned to the work are expected to handle instruments, sponges, dressings, etc., during the operation.

When any one taking part in the operation touches an object not sterilized, such as a table, a tray, or the ether towel, he should not be allowed to touch the instruments, the dressings, or the ligatures until his hands have been again sterilized. It is important that the hands of the surgeon, his assistants and nurses should not touch any part of his own or the patient's body, because infection may be carried to the wound. Rubbing the beard or head, or wiping the nose, requires immediate disinfection of the hands to be practiced.

The trailing ends of ligatures and sutures should never be allowed to touch an assistant's or surgeon's dress, or to drag upon the operating table because contact may occasionally, though not always, pick up bacteria, which may cause suppuration in the wound.

Instruments that fall upon the floor should not be again used until thoroughly disinfected. The clothing of the patient in the vicinity of the part to be operated upon, and the blankets and sheets used to keep him warm should be covered with dry sublimate towels, and all dressings should be kept safe from infection by being stored in glass jars or wrapped in dry sublimate towels.

THE PREVENTION OF THE SHORT LEG OF HIP DISEASE.

Read before the American Orthopaedic Association, at Boston, Mass., September 18, 1889.

BY A. B. JUDSON, M.D.,

ORTHOPÆDIC SURGEON TO THE OUT-PATIENT DEPARTMENT OF THE NEW YORK HOSPITAL.

A short leg is what is commonly dreaded as the result of hip disease. The shortening is not, however, as a rule, due to the shortening of the bones. What produces the short leg of hip disease is an immobilization of the joint which prevents the reduction of flexion of the thigh, or adduction of the thigh; or which, as too often happens, prevents the reduction of both flexion and adduction. If, for instance, the patient stands with the thigh considerably adducted, we will say 22.5 degrees, and fixed at that angle, the limb cannot be made vertical without elevation of that side of the pelvis, with of course a drawing upward of the heel and an inevitable appearance of shortening; and if the thigh is flexed, for example 45 degrees, and fixed at that angle, the limb cannot be made vertical without an inclination forward, which gives an appearance of shortening to the whole figure. Thus we see, that when the patient stands, adduction means "apparent shortening." The same is true of flexion. And when we direct our attention to the deformity which attends the patient when he walks, we see that the affected side dips at every step, and that when the limb comes into a vertical position, as it does at the critical moment when it is called upon to support the weight of the body, the pelvis rocks forward or laterally, or it may be in both directions at every step; and we have the characteristic gait of hip disease.

If, on the other hand, the thigh is immovable on the pelvis in a good position, neither adducted nor flexed, when the patient stands, the limb is vertical and the pelvis is level in all directions; and when the patient walks, the pelvis without any lateral tilting, rocks to and fro with a moderate motion, enough to allow the limb to swing backward and forward, by virtue of the mobility of the vertebral joints and the hip joint of the unaffected side, in the arc appropriate for locomotion in a comparatively easy and graceful way. Walking thus performed, is attended by no dipping of the affected side, and with no shortening except what may come from shortening of the bones or "real shortening."

How to secure this good position of the limb in a hip joint ankylosed by disease, is a question of great importance, second only to the question,

¹ In abdominal operations it is usually not necessary, and may be unwise, to use the ordinary chemical antiseptic solutions because of their irritant qualities. When used in the abdominal and pelvic cavities such solutions must be very weak; ordinarily, water ten-

dered sterile by boiling just before the operation, is the proper fluid for sponges, irrigation and instruments. The precautions as to cleansing the area of operations externally, and as to instruments, must be the same as in other operative procedures.

How can we promote resolution of the inflammation? I believe a good ultimate position of the limb can be obtained by inducing the patient to use the affected limb as much as possible in walking, of course protected from concussion by the hip crutch.

I do not mean to say that traction is useless as an agent for overcoming deformity; it will diminish extreme deformity with absolute certainty whether applied with the weight and pulley over rack and pinion; but it is less effective when the deformity is only moderate or slight. Applied, for instance, to an extreme case of flexion, it will produce extension. Indeed, traction, a few years ago, was universally called extension. But in proportion as the flexion is reduced, the power of traction to further reduce the deformity rapidly diminishes, because it is evident that a given power loses its ability to overcome resistance at the angle, as the angle becomes more obtuse. If, for instance, we would straighten a crooked nail we may, if the nail is very much bent, say at an angle of 90° , reduce the angle by traction; but as the angle becomes more and more obtuse, the power of traction to accomplish our object lessens, and finally disappears.

This consideration is one of those which lead me to discredit traction as a means of reducing deformity. Another, is the fact, that although traction may, in skilful hands overcome even slight degrees of deformity, it is only by assiduous attention and a nice adjustment of the direction in which the force is applied that this may be done. The correct position of the limb, thus brought about, is maintained while the patient is under special supervision and restraint; but when they are relaxed, the causes, whatever they may be, which produce the deviation, resume their influence. And this leads to the inquiry, What are the causes which produce the customary deformity of hip disease; what flexes and adducts the limb?

This question is quite distinct from the question, What prevents motion? We know that motion is prevented, first, by reflex contraction of the muscles, and afterward by ankylosis; but what determines the position of the limb through the months and years when muscular action holds it fixed; what forbids a good position and inclines toward adduction and flexion? If we can discover the forces which cause the limb to err, we may perhaps remove or thwart them. It has been said that effusion determines the direction of the limb, which takes that position in which the capsule can best accommodate the volume of fluid. Migration of the acetabulum and dislocation of the femoral head, have also been cited as controlling forces. Abduction has been thought to depend on spasm of the gluteal muscles followed by their paralysis, which allows their opposing muscles to produce adduction. Atrophy and attrition of the

head and acetabulum have been thought to have some effect in deciding the character of the deformity. It has also been said that the limb takes that position in which an imaginary painful spot or area on the head of the femur is furthest removed from the depth of the acetabulum, where it would receive pressure from muscular action.

In some stages, and in certain cases, each of these modes of accounting for the chosen position of the limb may, or may not, be correct; but what we want, is to recognize some cause, general in its application, and independent of such pathological conditions as have been cited, which are more or less transient and difficult to demonstrate in bone, muscle, nerve, or effused fluid. A more widely applicable theory is that which says the position is generally the attitude of minimum suffering; but pain is not always present, indeed, as a rule, it is present but a small portion of the time during which the limb is held in its selected position. Can we not find a cause which is in force in all the periods of the affection, the painless as well as the painful?

It has been said, and wisely, that the position is due to efforts made by the child and nature to secure fixation, and that the position assumed is that in which immobilization by nature reaches its maximum. This is a good explanation, and applicable to every case in all of its stages; but I do not think these words quite cover the whole ground. I would add to them a line recognizing the influence exerted on the direction of the limb by the patient's habitual attitudes and positions.

Before accepting this addition, however, it will be necessary for us to accustom ourselves to recognize the fact that the fixation or immobilization created by reflex muscular action is very far from being absolute immobility. This view is in accord with the ordinary events of practice. Cases in which fixedness is inconstant are matters of daily observation. For instance, a joint at the first moment of examination is without motion, but a few moments of delay and skilful manipulation reveal slight motion. Or, at one examination, the limb is in a position, adducted we will say, at a certain angle, which is made a matter of record, and at the next examination, a few hours or days later, the angle is widely increased or diminished. Or a patient with marked deformity is put to bed with a weight and pulley, or is treated by traction with the hip-splint, and the deformity is greatly mitigated in a few hours. In all these cases, reflex muscular action is in force, and yet it does not prohibit changes in the direction of the limb. The condition resembles that found in patients affected with a certain kind of paralysis, whose joints have been compared to a leaden pipe which retains its shape with a very positive degree of fixedness, but which can be bent by the application of a suitable degree of force.

In view of this mobility of the joint, fixed by reflex muscular action, I believe that the position assumed by the limb is determined by the patient's efforts, both voluntary and reflex, to place the limb where its fixation will be liable to the least disturbance, and where it will afford him the most convenience in his ordinary attitudes and movements.

Before considering how to avert deformity it is in order to review the typical positions of the limb in hip disease. They seem to be three in number, and arranged chronologically as follows: 1. Abduction, which is produced early in the disease, when the patient seeks to favor the limb when he stands by putting his weight on the sound limb. He assumes the attitude which follows the military order, "at rest," in which the limb is abducted with a descent of the pelvis on that side and apparent lengthening. Later in the progress of the disease, we have, 2. Adduction and flexion, caused by the patient's efforts to withdraw the affected limb from undue contact with the ground, and to make the disabled member as little an impediment as possible, while the chief work of progression is done by the sound limb. The natural rhythm of the gait is broken, the sound foot being on the ground longer than the other, and the affected limb is drawn up out of the way, when the foot is raised from the ground, by an elevation of the pelvis on that side, with of course, adduction and flexion of the thigh and apparent shortening. Finally, in the neglected and bed-ridden patient, we have, 3. Extreme flexion of the knee and thigh, and extreme adduction of the thigh, obviously the position in which the patient is most comfortable, and the joint most free from disturbance.

These changes, taking place in a typical and uninterrupted case, but illustrate the mobility of the immobilization, so to speak, which characterizes hip disease. In passing, would it not be well to agree to call this form of immobilization, "fixation," a term the status of which is not well established, leaving the longer word to be applied to absolute immobility, such as accompanies ankylosis or bony union after fracture? We could also use the term fixation to indicate what we produce in the hip-joint by traction, which is not absolute immobility, but enough immobilization to aid the natural efforts to keep the joint still and promote resolution, and yet not enough to stand in the way of desirable changes in the position of the limb.

To return to methods of averting deformity, the first position, that of abduction, seldom calls for attention in practice. It would, in some cases, be fortunate if slight abduction could be maintained as the ultimate position, because the apparent lengthening thus secured might happily compensate for whatever real shortening is entailed by the destruction or retarded growth of

the bone. The third position, extreme flexion and adduction, cannot occur with the use of the hip-splint; and as we all, I presume, adhere to treatment by this apparatus, the practical question before us concerns only the prevention of the second position, that in which the thigh is seriously but not extremely flexed and adducted. How can we then, by the use of the hip-splint, keep the limb slightly flexed and free from adduction during the many months which usually intervene between the first appearance of deformity and the occurrence of ankylosis?

To recall what we have said about the cause of this deformity, it is the result of the patient's efforts to keep the affected limb off the ground while the well limb does most of the work of progression. If then, we can induce the patient to adopt a gait in which the two limbs are used equally, the cause of the deformity would vanish. The affected limb would then reach for the ground at every step when its turn came, and that would mean a descent of the pelvis and the abolition of adduction, and this would be unattended with violence to the affected joint, because the weight of the body comes on the ischiatric tuberosity resting on the perineal strap, and not on the heel. The first, or an occasional effort of this kind, would not be likely to produce any effect, but if the effort is made habitual or a matter of systematic drill, the adduction of the limb will be gently and gradually corrected, because the patient, consciously or otherwise, will incline the limb towards abduction, so that he can more readily conform to the mode of walking prescribed for him. Undue flexion is subject to similar corrective procedures. And if the naturally rhythmical action of the limbs is restored and becomes habitual, the limb fixed in a good position by reflex muscular action, becomes immobilized by ankylosis, and the patient recovers with the minimum of deformity and locomotor disability.

It may be said, by the way, that the rhythm of the human gait is a subject which has not received the attention to which it is entitled. When natural, it is very simple, the time being divided equally between the two feet; but its very simplicity makes a slight deviation very noticeable, as in the lameness of incipient hip disease in a child, in whom the ordinary motions of the joint are as yet unlimited, and whose lameness is entirely due to the fact that he violates rhythm by spending more time on the sound than on the affected limb. He accents the blow given to the ground by the well foot, which hastens to relieve the affected limb of the weight of the body. It is a point of practical importance that many people who are lame, add to their lameness by neglecting to keep correct time with their feet. Any of us can appear lame by simply giving more time to one foot than to the other, a matter of easy and immediate demonstration; and one who

is really lame can lessen the appearance of being so by simply giving natural rhythm to the action of the feet.

I have been led to the opinions¹ presented in this paper by pondering the question, Why do patients similarly affected, and treated exactly alike, recover with such different degrees of deformity? A young girl, for instance, was in the third stage, in which she nearly lost her life, before treatment was begun. She has recovered with no adduction, and almost no flexion; so that although there is real shortening of nearly two inches, there is very little lameness. I attribute this good position to the fact that her mother was very anxious about her only daughter, and was always with her, so that every step the child took with the hip splint was taken under the necessity of appearing as well as she could. Her steps were equally timed, and the affected limb became ankylosed in a useful position because it had to do, so far as was possible, half the work of locomotion. I also treated a boy who recovered from the disease, in a more moderate although purulent form; but he limps about most awkwardly with 20 degrees of adduction, and 50 degrees of flexion. I explain his bad position by the fact that the mother, one of the best of women, was busy out of the house, every day, and nearly all day, necessarily leaving at home and very much to their own devices, her family of four boys. As the patient was most of the time in excellent general health and very ambitious, he vied with his brothers in all their games, and developed his well limb enormously at the expense of the affected one, which was elevated and adducted to keep it out of the way. In another case the patient, who recovered after long-continued purulent discharges, was a girl endowed with uncommon beauty; and although she was by no means docile, and under very little restraint at home, her vanity led her to try always to appear at the best advantage, and thanks to her careful gait and studied attempts to be graceful, she now walks with very little lameness, with flexion not more than 10 degrees, adduction *nil*, and more than two inches of real shortening.

Another child, whose treatment as a hospital out-patient was finally suspended for neglect, will probably recover with the limb adducted forty-five degrees. A year before her final discharge she was made an in-patient and the deformity was entirely reduced by recumbency and the weight and pulley for seven weeks; but soon after returning to her unfortunate home, where a large family and poverty make even ordinary parental care impossible, the deformity recurred and will doubtless be permanent.

These are the more striking examples selected

from many cases, the study of which has led me to the practical conclusions above expressed. I believe that for years I made a mistake by encouraging patients, protected by the hip splint, to take part in the rough occupations of healthy children. One result was frequent chafing by the perineal straps, which at once destroys correct rhythm, because it is impossible for the patient to divide his weight equally between the well foot on the one side, and the excoriated perineum on the other. It is my practice now to advise moderation in exercise, and especial attention to the manner of walking. I insist on the patient's keeping time in his steps so far as practicable, and lead him to adopt and maintain a proud bearing, keeping his head high and behind the vertical of the centre of gravity. A girl is told to practice deportment before the looking glass, and a boy is advised to organize a juvenile military company, and to take command of it himself. The parents are informed of the importance of encouraging the child to adopt deliberate and graceful movements on all occasions. Since I have changed my practice in this regard, there has been an improvement in results, and I no longer am anxious as to the ultimate position except in those cases in which the patient is intractable, and the domestic management at fault.

It may be well to mention that, as in this method of regulating the position of the limb no account is made of the abductive power of the traction by the hip splint, the perineal strap on the sound side is dispensed with. A single strap is more convenient, and has proved sufficient both as an ischiatic crutch and an agent for making counter traction when the rack and pinion are used.

Summary.—The deformities of hip disease are caused by the patient's efforts to so place the limb that it shall be the least disturbed by, and afford him the most convenience in his customary attitudes and movements. They are, 1. Abduction; 2. Adduction and flexion; and 3. Extreme adduction and flexion. The second position is practically by far the most important, and is the only one considered in this paper. It is caused by the patient's elevating that side of the pelvis in order to take the limb off the ground, and to keep the affected limb out of the way of the well one, which is on the ground a longer time than the affected limb, and does most of the work of progression. The limb is maintained in the chosen position by reflex muscular contraction, which does not immobilize the joint, but fixes it in such a manner that changes in its position are readily made by the application of gentle but persistent force. It is proposed therefore, to induce the patient, wearing the hip splint, which protects the joint from the violence of walking, to divide the time on the ground equally between the two feet, or rather between the foot of the sound side and

¹ Medical Record, May 21, 1887, p. 386, St. Louis Courier of Medicine, May, 1881, p. 372.

the ischiatic crutch on the affected side, with the expectation that adduction and flexion will be wholly or in part reduced, when the affected limb makes repeated efforts to reach the ground and do its share in locomotion. It is believed that the patient can be induced by precept and drill to adopt this manner of locomotion with the result indicated, a belief which is sustained by the observation that patients led by accident to walk in this way, have recovered with a good position of the limb, and by the results of the adoption in practice of this method of preventing deformity.

4 East 25th St., Madison Square, New York City.

MALIGNANT SMALL-POX: A FORM HITHERTO FATAL.

BY H. RUSSELL, M.D.,

OF SUPERIOR, WIS.

FORMERLY FIRST ASSIST SURGEON 35TH WISCONSIN VOLUNTEERS.

I take the liberty of sending you a report of some cases of above form of small-pox for publication in your valuable journal, in order to expose to the notice of the medical profession a pretty accurate description thereof and its treatment, so that the disease may be diagnosed, if possible, at time of physician's first visit and thereby not permitted to spread, which state of matters occurred after the first case of it, which I saw in vicinity of Westfield, Marquette Co., Wisconsin, in the winter of 1872-73, as, although prior thereto, I had seen many cases of variola and varioloid, I totally failed to discern the least resemblance to last diseases.

My first case was that of a young man, named James Brown, whom I first visited on the 18th of January, 1873, and found in the usual febrile state, precursory to an eruptive disease, with an eruption just appearing on the forehead, which I considered as having been that of scarlatina and announced it as such to his parents, but on the following day the patches were larger than those of scarlatina, and, after having looked over the various exanthema in Aitken's "Practice," I concluded that it was a case of hybrid, described therein, and watched its progress carefully for a few days, when I told them that I did not know the name of the disease that affected their son and advised counsel, which was not obtained, and on the following Monday another physician took charge of the case and diagnosed it as black measles, and as no one was afraid of measles, many visited the patient; hence, in about two weeks thereafter there were many affected by variola, varioloid, and referred to malignant form, and, knowing that the treatment of the first two is simple, and that the character of the pustules, etc., attending them is easily detectible and recognizable by physicians and others who have, previously, seen such cases, I shall, in the follow-

ing, try to describe the appearance of the pustules in said form, its history and the treatment which I found to be of service in my last case, and the only one in which I tried it to any amount.

The pustules, if such they may be termed, in this almost hitherto, nondescript, are not cone-shaped as in variola, and varioloid, but are umbilicated in the centres, of about the size of an ordinary cowpock, are red around the bases and marginally contain a clear fluid which scarcely ever becomes opaque in the least, are mostly confined to the face and extremities, whilst the whole trunk, as far down as the umbilicus, is of a bright red color, and in no case need the attending physician expect such a patient to live more than ten or ten and one-half days after the first appearance of the eruption by using ordinary treatment; such, at least, having been my experience; but in my last case, that of a child named Hannah Smith, aged 9 years, I used tincture of iodine, of which I gave her eight drops in syrup every three hours, and am happy to state that she recovered as readily as if she had merely been affected with measles, whereas her brother and sister had succumbed to the same fatal form, the former not having taken any iodine and been treated by another physician, and the latter only having used it for the period of three or four days prior to death.

In regard to the use of iodine in this form of small-pox, I would say that I got the idea from having seen Prof. Daniel Brainard, of Chicago, successfully use it, hypodermically, on chickens, in the presence of his class for the bite of the rattlesnake, and having used in my former cases, of which I had thirteen during said winter, the different acids, etc., and hydrate of chloral (said to have been used beneficially in the German army for small pox), without the least success, I happened to think of the iodine, and presumed that, as it had acted so well against rattlesnake poison, it might, possibly, have a good effect on small pox poison, and hence, used it with the above happy result, and it is my opinion, that if I had used it in my former cases I would have saved all of their lives except those of two, who, during the continuance of the disease, were affected by severe intestinal hæmorrhage.

In regard to the terrible affection being a new one, I have very good reason to believe that it was in the north of Ireland about seventy-nine years since, and in other parts of Europe about one hundred and sixty-nine years ago, and wonder why a very accurate description of it is not to be found to day in every standard work on the practice of medicine, whereas it is not in any of them unless in one lately published by that talented, time-honored veteran, Prof. N. S. Davis, of Chicago, and is by all odds, more fatal than any and all of the pustular or exanthematous

diseases. The only cases of it of which I have read a description, were those of two published by him in an issue of *THE JOURNAL* in 1872; his description was very fine, and he described them under the heading of "new diseases," and stated that the first terminated fatally from intestinal hæmorrhage and that he sent the second to the pest-house and did not know the result thereof.

The *New York Sun*, in 1873, published a history of the disease as having been known in the countries referred to above, and at said periods, and I also obtained from an old reliable gentleman, named James Hamilton, formerly of County Down, Ireland, a verbal statement in which he said that he recollected, when a "wee boy" that such a form of small-pox was in the north of Ireland at the same time as stated by the *Sun*, and that all cases of it were invariably fatal. I might also say that in all of my fourteen cases none had been successfully vaccinated and would, therefore, respectfully suggest that stringent, general, State and local enactments be immediately passed for the very charitable and life-saving purpose of carrying out the entire vaccination of all parties not vaccinated as, owing to the small number that were exposed to my first case of malignant small-pox with the result of thirteen having contracted same fatal form and sixteen-four been affected with variola and varioloid during the continuance of the disease in said winter, it is my humble opinion that to-day there are not less than ten millions of people in the United States who are liable at any time to contract said fatal form. I might, also, say that in a newspaper in 1873, I read an account of a case of it having occurred in Indiana with the same result as in my first case but whether it was published in a medical journal or not I do not know. That said disease might, with propriety, be called black small-pox, especially in the fatal cases, as in each and all of those which I treated, about the second day prior to death the face and surface generally began to assume a dark color, which continued to become more so gradually until the patient for hours before death appeared almost as black as a negro, and that in each of my fatal cases each doomed patient several hours before death, realized that he or she was about to die and told relatives the manner in which they desired their property to be divided, whilst at the same time I could not yet infer from the character of the pulse nor respiration that my patient was commencing to fail.

NOT A BAD IDEA.—A. Oakes Hall, one of the ex-mayors of New York, in one of his London contributions to the *N. Y. Press*, suggests a statue of Dr. Valentine Mott, to be erected in the Central Park. In the metropolitan city, however, all memorials are of rather tardy growth.

A CASE OF ACUTE INTESTINAL OBSTRUCTION.

Read before the Kings County Medical Association, March 2, 1889.

BY F. C. RAYNOR, M.D.,
OF BROOKLYN, N. Y.

The following history of a case, which I present for discussion, is of interest, *first*, from the difficulty in making a diagnosis; *secondly*, from the manner in which the obstruction was produced; *thirdly*, from the amount of intestine occluded.

The patient, a colored woman, aged 57, weighing about 175 lbs., single, and a cook by occupation, was taken, two days before I was called, with a sudden and severe pain while ascending the stairs, and it was some little time before she was able to proceed, and then with much difficulty she reached her room. Later she had occasional colicky pains, and vomited some biliary matter. As the bowels had not moved for several days, she was given an enema, which only brought away a few hard fecal masses. For her pain she had been using hot applications. These symptoms continuing, I was sent for. On my first visit, May 21, 1889, I found her complaining as above, with a normal temperature, and a fairly strong pulse of 70. The abdomen was slightly distended, and she had some general soreness, but there was no marked tenderness, and on firm pressure I could detect no sensitive spot. There was no local tumefaction that I could detect, and the external abdominal rings were normal. A careful vaginal and rectal examination was made with a negative result. As she had been subject to what she called "bilious attacks" and further, being under the impression that she had worms, had taken at intervals for years past about all the different vermifuges on the market, it was my opinion she was suffering from some digestive derangement due to improper eating and over-medication. Accordingly, I prescribed a sedative and a diet of milk and Vichy. On the 22d the temperature was normal, pulse 74. The stomach rejected all food taken, and she frequently vomited biliary matter. I continued the sedative and prescribed a cathartic. 23d. No effect from the cathartic, vomiting continues, some hiccup, temperature 97°, pulse 104 and weak. Continued sedative and ordered beef peptonoids and brandy, per rectum. 24th. Patient weaker, vomiting persists, and for the first time is stercoraceous; has passed flatus twice. I then knew I had some form of intestinal obstruction to deal with, but what? At this visit the temperature was 98°, pulse 108. Treatment continued. 25th. Has not vomited in twenty-four hours, and bowels moved freely, passing formed and semi liquid stools with considerable flatus, slept well during the night, has no pain, and feeling stronger. Temperature 99°, pulse 100. I then was of the

opinion that the obstruction was a volvulus, and that it had been spontaneously relieved, and I felt more hopeful of the case. 26th, General condition somewhat improved; retains food and stimulants. 27th, Still retains food and stimulants, but is weaker. At my evening visit I found her in collapse; she was suffering no pain, was somewhat restless, but her mind was clear. She did not respond to treatment and died at 5 o'clock A.M. on the 28th. A partial autopsy was permitted, and revealed the following: The abdominal walls were two inches thick; no fluid in the peritoneal cavity; peritoneum normal; omentum containing a large amount of fat. On the right side was an incipient hernia, which barely entered the inguinal canal. The gut at a point opposite to the mesentery was so firmly adherent to the margin of the internal ring that it could not be separated. It was twisted on itself, and gangrenous where twisted to the extent of about one square inch. It was not constricted in the ring, and when untwisted, the canal was pervious. The mesentery of the adherent gut formed a constricting band which, extending across to the last lumbar vertebra, passed one inch to the left side of the caput coli, and occluded eleven feet of ileum. The lower half of the large intestine was empty; the upper contained solid feces; stomach and small intestine above the constriction contained fluid; other organs not examined.

Let us review briefly, on the authority of Erichsen, the more usual causes of acute intestinal obstruction with their diagnostic symptoms. 1. We may have internal strangulation from a portion of the gut slipping through an aperture in the mesentery or omentum, forming the so called internal hernia; or a portion of the intestine may be constricted by becoming entangled round a band passing from one part of the abdominal cavity to another; these bands may be from old peritonitic adhesions, from the vermiform appendix, or a diverticulum from the ileum, the free end of which has become attached to some part of the abdominal wall. 2. Volvulus. 3. Stricture which, gradually closing, becomes suddenly obstructed. 4. Foreign bodies. 5. Inflammatory affections. 6. Intussusception. As there was no history to suggest the third, fourth and fifth causes, we can exclude them and confine ourselves to the first, second and sixth. The symptoms common to all are, severe pain coming on suddenly, followed by early collapse; the pulse is quickened, temperature at first slightly elevated, but soon becoming subnormal; acute abdominal pain fixed in one spot with paroxysmal exacerbations; early severe vomiting, becoming stercoraceous speedily, if the obstruction is in the small intestine, or after several days if the large intestine is occluded; complete constipation; marked abdominal distension.

In thin subjects coils of intestine and peristalsis may be observed through the abdominal walls.

In volvulus the twist is generally in the sigmoid flexure, or the descending colon, and the pain will be referred to that region. Peristalsis is said to be greatest in this variety of obstruction. In intussusception, in addition to the foregoing there is, at the seat of the obstruction, a sausage-shaped tumor, doughy to the feel, which becomes tense on manipulation, owing to the peristaltic contraction of the gut, which is thereby excited. It is tender, and the contractions are accompanied by griping pains. There may be also tenesmus, and a discharge of bloody mucus. The other authorities that I have consulted agree substantially with the above. Comparing this description with my case, which was both a volvulus of the small intestine and a constricting band—for I do not regard the hernia *per se*, a cause of the obstruction—we note an absence of any fixed pain, great abdominal distension, or any local tumefaction or point of tenderness, and although the obstruction was high up in the ileum, stercoraceous vomiting did not occur until the fifth day. The pulse and temperature were also at variance with the description given. But the most misleading symptoms were the passing of feces and flatus, in considerable quantities, on the sixth day, together with an improvement in the general condition, making it appear that the obstruction had been removed. I can only account for it by assuming that the discharge came entirely from the large intestine, and was occasioned by a local peristalsis.

On reviewing the case I am of the opinion that the hernia had been a long time adherent, and occasioned the symptoms which she attributed to worms, and the obstruction was caused by the intestine becoming entangled around the mesenteric band, and which, twisting the gut on itself, produced the volvulus. In regard to the propriety of surgical interference in the treatment of the case, it seems to me that the symptoms at first did not warrant an explorative laparotomy, and when dangerous symptoms did appear they were apparently relieved spontaneously within twenty-four hours, and from the conditions found at the autopsy, it is questionable if an operation could have been successfully performed.

OVARIOTOMY AS A PROPHYLAXIS AND CURE FOR INSANITY.

BY ROBERT A. KITTO, M.D.,

OF RACINE, WIS.

I desire to present to the readers of THE JOURNAL a very interesting case of pseudo-insanity which I recently cured by removing both ovaries with their tubes, bringing about a complete restoration of a mind which had been under a cloud for thirteen years, and which had been pronounced incurable insanity.

Miss Ada M., Racine, Wis., age 25, brunette, full habit, fair health. When she was thirteen years old she had a severe attack of scarlet fever which left her in a very unsound condition of mind. From the age of 14 she began to show signs of unsoundness of mind, which grew rapidly worse until she was 18, when she became so violent and unmanageable that her parents were obliged to apply for a medical commission to examine into her mental condition with a view of sending her to an asylum, which was accordingly done. She was committed to Oshkosh (Wis.) Asylum in 1887. There she remained under regular treatment for a period of eight months, when she was discharged and sent home. She was, however, by no means cured, as she almost immediately began to show signs of a return of her former trouble, and after a space of two years she was again committed to the same asylum for treatment, where she remained for a space of one year; she was again returned home, but remained in a semi-sane condition, being not violent, but so much deranged that it was found necessary to confine her to the house. She would often escape into the street in almost a nude condition; she would scream, dance, laugh and cry just as the fancy took her. She complained constantly of a pain in the groin and region of the womb, she had had a constant discharge of acrid pus per vaginam. Her menses were irregular from the first of their appearance, which was at the age of 14. She would often ask her attendants if there was no help for her. She was treated by various local physicians with but little benefit for several years. She had grown old-looking and very idiotic, she had lost all self-control and was decidedly childish.

She came under my care in September, 1890. I made a careful examination and diagnosed the case as hysterical insanity and advised ovariectomy, believing that her ovaries and tubes were diseased from the symptoms. I was met by stern opposition from members of the family, also from various counseling doctors. I finally sent her to a prominent specialist in Chicago, who decided it was a hopeless case of brain disease. The unfortunate girl heard the eminent specialist pronounce her doom, and came home much depressed and grew violent and wholly uncontrollable.

It was January 4 of the present year that, after such good counsel, her parents decided to send her again, for life, to the insane asylum. I remonstrated with them, and finally persuaded them to allow me to operate and remove her ovaries, which they did. Accordingly, on February 4, I performed the operation with the above result, for which both the patient and myself have much reason to feel gratified, for she is now entirely well, mentally and physically.

The usual steps of the operation being familiar to all, I shall not take time nor space to dwell

upon. The usual incision was made and the organs accordingly removed with the tubes. I found, as I had predicted, that both ovaries were in a state of chronic inflammation, also the tubes were in a state of pyosalpinx. A thimbleful of acrid pus escaped from each ovary in removing them, they having grown extensively on the bowels and surrounding pelvic tissues, which necessitated considerable tearing in order to remove them. An accident which is much dreaded by surgeons, and a most formidable one too, occurred in trying to tear the ovaries from the intestines. I accidentally tore the gut, which was followed by an escape of fecal matter and gas. Being prepared for such an accident, I at once proceeded to close the lacerated gut, which was done by simply excising the lacerated edges and putting in the Czerny and Lembert suture of silk. The wound closed, I proceeded to complete the operation by removing the other ovary with its tube, which was done without a similar accident. When I closed the wound and applied the usual dressing, I put the patient to bed, applied hot bottles and gave a full hypodermic injection of morphia, $\frac{1}{3}$ gr. She emerged from the chloroform in due time, and upon fully awaking she looked about her, but not with the former idiotic gaze, but a serene calmness which was remarked by the attending physicians. She said, "Dr. Kitto, have you succeeded in removing the offending appendages?" Being answered in the affirmative, she smiled and said, "I am so happy, and I feel so different that I know I shall now remain well." While this will be read with much doubt by some, yet I must insist upon the fact that it was none the less true. She continued to improve from that day on, which is now four weeks. She has been discharged from the hospital cured mentally and physically.

I believe this case will do much to establish my theory, that hundreds of unfortunate women are to day languishing in insane asylums, who might be cured by a similar operation.

This goes to show that this and many hundreds of such cases are not insane, in the usual acceptation of the term, but are subjects of reflex irritations.

I have not further time to-day to dwell upon this important case, but will write again on this subject, touching upon diagnosis and proper selection of cases for the knife.

March 2, 1891.

GERMAN OPPOSITION TO WOMEN IN THE PRACTICE OF MEDICINE.—A discussion occurred in the German Reichstag on March 11, touching the admission of women to the liberal professions, during which Herr Schröder urged that the government should open the way, and offer opportunities, for women in the practice of medicine. The House declared itself against the petition.

MEDICAL PROGRESS.

Therapeutics and Pharmacology.

TRICHLORACETIC ACID.—EHRMANN (*L'Union Médicale*, Feb. 28, 1891) has employed this agent in the treatment of diseases of the nose and throat. Touching the affected parts with a crystal produces a white eschar, strictly localized, rapidly detached, and free from secondary irritation or inflammation. Of 140 cases, 87 required cauterizing but once, 30 were treated twice, and a few resisting cases from three to five times. A permanent cure was effected in 122 cases. Ehrmann is of the opinion that this substance is of the first rank in the treatment of diseases of the throat and nose.

Trichloroacetic acid may also be employed as an astringent, according to the following formula: Iodine 15 grams, iodide of potassium 20 grams, trichloroacetic acid 15 to 30 grams, glycerine 30 grams, to be applied to the affected part upon pledgets of cotton.

THE OPEN TREATMENT OF PULMONARY CAVITIES.—PROFESSOR SONNENBURG reports five cases in which he opened pulmonary cavities from the outside as a preliminary to treatment by injections of tuberculin (*Die Wirksamkeit des Koch'schen Heilmittels gegen Tuberculose. Amtliche Berichte, etc.*, p. 837, *et seq.*). His method of procedure and the immediate results of the operation in the first four cases have already been described (*Supplement*, January 17, 1891, p. 21). As soon as the slight reaction following the incision has subsided the injections are begun, and Sonnenburg says their effect can be followed as readily as on the skin and mucous membrane. The action of the remedy was well displayed in the case last operated on in which a cavity in the right apex was laid open. For a fortnight after the operation Koch's treatment was not employed. In strong contrast to what occurred in the other cases, the cavity remained greasy and discolored, did not become clean, and showed no tendency to heal. As soon as the injections were begun the cavity was transformed into a healthy granulating wound. In all the cases a considerable amount of necrotic lung tissue was expelled, after which the cavities began to shrink; and, with regard to three of the patients, "one can already speak of almost complete cure." The result of the combinations of the injections with incision of pulmonary cavities has been to convince Sonnenburg that the treatment presents no danger, and offers good hopes of cure. In the three successful cases the general condition has improved; there are fewer tubercle bacilli in the sputum, and the patients have gained weight. Sonnenburg adds that further experience is required before trustworthy rules can be laid down for the guid-

ance of the practitioner in the selection of suitable cases for the surgical treatment of pulmonary cavities. Much also has still to be learnt as to the right method of using tuberculin, particularly as to individualizing the treatment. —*British Medical Journal*.

Surgery.

THE PATHOLOGY AND SURGERY OF THE APPENDIX CÆCI.—Although the Clinical Society departed from its usual course and devoted a meeting recently to an adjourned discussion on the above subject, yet it must have been felt at its close that the question had been by no means exhausted. It is one that has of late years come prominently to the front—one, too, in which both physicians and surgeons have an interest. It deals, moreover, with a class of disease of singular frequency, and of varying fatality. To discuss it adequately would require a debate much more prolonged than that which has just been assigned to it. We will therefore content ourselves here with noting some of the points raised in the course of that discussion. In the first place is to be remarked the want of unanimity upon the true nature of so-called typhlitis—a term which is, in the opinion of some, misapplied to the larger proportion of cases that are at present included under it. Although Mr. Treves has apparently gone back from his former belief as to the frequency with which the appendix shares in the production of the symptoms of typhlitis, and although, as Mr. Pearce Gould showed, the diagnosis of "appendicitis" had in some quarters been often very erroneously made, still there is no question that the pathological evidence of an independent inflammation of the body of the cæcum is as rare as the verification of an inflamed and ulcerated appendix in cases of "typhlitis" is common. Drs. Coupland and Kingston Fowler expressed this view strongly, the latter dealing with definite post-mortem facts. Mr. Treves laid some stress upon the palpation of an enlarged appendix through the rectum as serving to distinguish the cases; but he did not state whether this plan had been adopted in the ordinary cases, which recover under the guiding principles of "rest;" and it is certain that "relapsing" cases form no very large proportion of all those in which there is appendix mischief, nor, indeed, that there is more danger in a relapse than in a primary attack. On the whole, it will conduce to lucidity if we regard the appendix as the seat of the trouble in all classes of cases—those which resolve and those which lead to more or less extensive perityphlitic suppuration. Mr. Bland Sutton's comparison of the appendix to the tonsil was suggestive, but hardly essential to the argument. For although, as he showed, this structure is richly provided with lymphatic tissue, yet it is by no means certain that its inflammatory lesions are primarily

evolved and not excited by fecal or other impacted contents. As to the results of inflammation and ulceration of this structure, the cases may be grouped under the following heads: 1. Cases where perforation occurs suddenly, leading to general peritonitis. 2. Cases where the surrounding inflammation is limited, owing to the formation of adhesions. This class may be further subdivided into (*a*) those where there is resolution of the inflamed products, with or without a liability to relapse; and (*b*) those where suppuration takes place, the ultimate issue being uncertain, the pus sometimes burrowing into the tissues outside the peritoneum in various directions, sometimes being more or less confined within a peritoneal abscess, the existence of which is a constant element of danger to life. There can be no hesitation as to the propriety of surgical intervention in these latter cases; but the fact that the progress of the suppurative inflammation is often very insidious emphasizes the need for a prompt recourse to surgery whenever possible. A highly interesting point was raised by Mr. Pearce Gould—namely: whether the diseased appendix should be removed or not. He advocated the latter course, trusting to free incision and drainage, and he was supported by Mr. Charters Symonds; whilst Mr. Sutton, in his able reply, contended that this would hardly be an advance upon the old practice, and that it would be wrong to leave behind the source of irritation. The final decision in this matter must be left to the teachings of experience. One thing at any rate may be hoped for as the result of this debate, and that is a prompt resort to surgical interference when the indications point to extension of the inflammatory process to the general peritoneum or the supervention of suppuration.—*The Lancet*.

RESULTS OF OPERATIONS UPON TUBERCULOUS LYMPHATIC GLANDS.—NOORDEN (*Beitrag zur Klin. Chirurgie*) gives the results in 149 cases that were operated in the clinic of Tübingen. Only those cases were tabulated in which three years or more had elapsed since operation—93 cases were free from any return of the disease at periods varying from three to fourteen years. In 30 cases the disease returned, with local manifestations; 31 cases died within sixteen years of operation. In no case was there a return of the disease later than six years after operation. The writer reckons that 28 per cent. of all patients suffering from lymph adenoma die of other forms of tuberculosis. The most usual form of which is phthisis pulmonalis, and the writer recommends the early extirpation of enlarged glands, to protect the patient from a general systemic infection.

Physiology.

RECENT EXPERIMENTS ON THE CERVICAL SYMPATHETIC AND SYMPATHETIC GANGLIA.—The

existence of vasomotor fibres for the iris, and certain secretory fibres for the salivary glands in the cervical sympathetic nerve is well known. Luchsinger several years ago found that the cervical sympathetic also contains secretory fibres for the glands in the muzzle of the ox. Arloing (*Archives de Physiologie*, ii, 1890, p. 1) confirms the existence of these fibres; but he finds that inhibitory secretory fibres are also present in the same nerves. Ten minutes or so after section of the vago-sympathetic nerve in the ox the muzzle of that side becomes dry. Twenty to forty days after section of the cervical sympathetic, or rather the vago-sympathetic, nerve, stimulation of it is without effect; but if pilocarpin be injected there is active secretion in the glands in both sides of the muzzle, but the secretion is more pronounced on the side on which the nerve is divided. According to Arloing, the result is not due to vasomotor effects, but is to be explained by the inhibitory influences of the inhibitory secretory fibres disappearing with the degeneration of the inhibitory nerve fibres. An increased secretion of tears and also of the secretion of the Meibomian glands occurs after section of the cervical sympathetic, and the secretion is further increased by pilocarpin. Arloing regards these glands as receiving more inhibitory than secretion-exciting fibres. Hirschmann some years ago showed that after nicotine was given to an animal the cervical sympathetic lost its effect on the pupil. Langley and Dickinson (On the Local Paralysis of Peripheral Ganglia, etc., *Proc. Roy. Soc.*, vol. xlv, p. 423) find, however, that in the rabbit stimulation of the nerve above the superior cervical ganglia causes dilatation of the pupil. What, however, constitutes the chief interest in their observations is the local action of nicotine. If a 1 per cent. solution of this drug be pencilled on the superior cervical ganglion, stimulation of the nerve below the ganglion or of the ganglion is without effect on the iris. Nicotine, however, when applied locally to the nerve above the ganglion, has no effect on the nerve. Nicotine applied locally to the ganglion prevents stimulation below the ganglion from having its usual vasomotor effect on the blood vessels of the ear, and in addition the secretory action on the salivary gland is also arrested. The authors conclude that the sympathetic fibres for the blood vessels of the ear, the fibres for the iris, and the secretory fibres for the salivary glands, end in the nerve cells of the superior cervical ganglion, and from these nerve cells fibres proceed to their regions of distribution. Similar results were obtained by experiments on the solar plexus, that is, the local application of nicotine prevented the inhibitory effect of the splanchnic nerve on the movements of the intestine and stomach. Beyond the ganglion the fibres were active. The authors conclude that the inhibitory fibres of the splanchnic for the stomach end in

the nerve cells of the celiac ganglion, and those for the intestine in the superior mesenteric ganglion. Even when both plexuses are eliminated by the local action of nicotine, stimulation of the vagus still causes movements of the stomach and intestine, so that it is concluded that the vagus does not form connections with the nerve cells of these two plexuses. The vasomotor fibres, however, appear to end in or form connections with the nerve cells in these plexuses. In a later research (*Archives de Physiol.*, No. 1, January, 1891, p. 160) Arloing gives an account of continuation of his researches on the cervical sympathetic nerve, and in this paper he cites experiments which lead him to believe that trophic nerve fibres are also present in this nerve. The experiments were made on the ox and dog. In the muzzle of the ox marked histological changes in the papillae and stratum granulosum follow upon section of this nerve. In the dog after section of the vago-sympathetic nerve, the humidity on the muzzle is not altered, nor does galvanic stimulation of the nerve or injection of pilocarpin increase the moisture, these results being due to the absence of glands in the more hairy part of the dog's nose, while such glands are abundant in the muzzle of the ox. After two months or so, however, there are marked changes in the nose of the dog, the skin becomes papillated and dry, while there is great hypertrophy of the corneous layer. Arloing concludes from his experiments that the cervical sympathetic nerve in the ox and dog contains trophic fibres for the glands and epithelium in the former, and for the epithelium in the latter; and that their action is independent of the vaso motor and glandular nerve fibres.—*Brit. Med. Journal*.

POWERS OF PERCEPTION OF CHILDREN.—BINET (*Revue Philosophique*, December, 1890) has made a series of very interesting observations on the powers of perception of children. He experimented upon two little sisters, and found that the first color to be recognized was invariably red. When between 1 and 2 years old they could easily recognize the entire figure drawn on paper in outline of some common object, as a man, but it was several years before they could with certainty recognize an outline drawing of some individual part—as an ear or a finger. Binet also investigated how far the ideas of children are spontaneous, and how far they are recollections of dreams, but he found it difficult to come to any conclusion. He points out that at first children always regard themselves in the third person, and he gives several interesting conversations which show that their ideas about all objects are utilitarian; for example, they look upon a knife as a thing to cut with, bread as something to be eaten, and so on.

Pathology.

THE MICROÖRGANISMS OF CANCER.—DR. SCHUTZ (*Centralbl. f. Chir.*, January 24th, 1891), whilst fully recognizing the appearances which have been described by several authors as occurring in cancer, does not, however, regard the bodies in question as living organisms, but thinks it far more probable that they are formed (in part, at least) of red blood corpuscles which, both in carcinoma and sarcoma, find their way freely into the tissues and assume various disguises, so that their origin is not easily determined. Another source of the so-called organisms depends, he asserts, on the alteration of the cells of the various tissues which take upon themselves amoeboid movement, and congregate oftentimes in masses; and it is by the alteration of these masses that the so-called sporocysts are formed. So far, he is of opinion we are as far as ever from finding the true organism which produces cancer, even supposing that it exists.—*Brit. Med. Journal*.

THE BLOOD IN PNEUMONIA.—DR. KIKODZE has published in the *Bolnichnaya Gazeta* of Dr. Botkin, some interesting observations on the blood during pneumonia. He found that during the course of this disease the white corpuscles increase in number to as much as double, or even treble, what they are in healthy persons. The increase is observed in the fully mature and over-mature corpuscles rather than in the young ones. It is worthy of note that in fatal and very severe cases no increase in the white corpuscles is found. As a rule, however, the increase begins even before the physical signs of pneumonia are detected. It persists from that time onward without any great variations to the crisis, immediately after which it suddenly falls.—*Lancet*.

Hygiene.

TYPHOID BACILLUS IN DRINKING WATER. DR. FINKELNBURG (*Centralblatt für Bakteriologie und Parasitenkunde*, March 7, 1891) mentions an instance in which he examined a suspected water and found no bacilli by the ordinary method—mixing a cubic-centimetre of the water with nutritive gelatine and spreading out upon plates. By the use of his settling apparatus (described in the *Corresp.-blatt des niederrhein. Vereins für öff. Ges. Hygiene*, Band 11) there developed in the cultures colonies of bacteria, that appeared to be identical with Eberth's typhoid bacillus. Within a few years the writer has examined fifteen samples of water thought to contain the typhoid bacillus in which the ordinary method of examination gave negative results, but the application of the settling method demonstrated on the first trial the presence of the bacillus. He thinks the use of this method would in many instances demonstrate pathogenic organisms in waters, which are now pronounced free from contamination.

 NO. 65 WABASH AVE.,

CHICAGO, ILLINOIS.

All members of the Association should send their Annual *Dues* to the Treasurer, Richard J. Dunglison, M.D., Lock Box 1274, Philadelphia, Pa.

LONDON OFFICE, 57 AND 59 LUDGATE HILL.

SATURDAY, APRIL 11, 1891.

THE FURTHER DEVELOPMENT OF THE SECTIONS.

It seems to us that the time has arrived when the question should be carefully considered by the members of the Association, as to the best method of developing the work of the Sections, of presenting that work at the annual meetings, and of preparing the same for publication.

Faithful as its officers have been, and liberal in the expenditure of money as some of the officers of Sections are, in the effort to secure a proper reporting of their proceedings, still we doubt if in any instance they have been fully satisfied with the results they sought to accomplish. The fault was certainly not with them, but in so far as there was failure it was inherent to our present method of securing and presenting, discussing and publishing our papers.

It was with no ordinary effort that the Sections, now eleven in number, were inaugurated and brought into their present working order. Thus far, probably, the present methods were the best that we could hope to secure. But now that the Sections are firmly and permanently established, it seems desirable to carefully consider to what extent and in what respects modifications may be made which may remedy existing evils, and enhance the general good. With this in view, and with no purpose to undo what has already been so well done, we desire to offer for the consideration of our members the following suggestions:

1. With reference to the preparation and pre-

sentation of papers. Practically, at the annual meetings there are three working sessions of the Sections, extra sessions not included, of about three hours each, giving at the most from ten to twelve hours for the presentation of papers. If the length of these papers be limited to twenty minutes each, and the discussion of each paper to the same length of time, not more than fifteen papers can be profitably presented in any one Section. This would give an aggregate of at least one hundred and fifty papers for publication, which, with the discussions properly reported, would fully occupy the pages devoted to the publication of "Original" matter in THE JOURNAL for the entire year.

Of a given fifteen papers in a Section at least ten could be assigned to men of known ability in token of honorable recognition. It should be accounted a matter of honor—also, if a man be assigned to the discussion of a given paper, and if each fulfill his engagement, every paper would secure appropriate consideration. Five volunteer papers could also be presented, thus giving abundant opportunity for individuals desiring to present special subjects to come before the Sections, such volunteer papers or full abstracts of the same being first submitted to a constituted board for their approval. No papers should be read simply by title and referred to the publishing committee, nor should papers be announced in the programme unless there is reasonable assurance that they will be read in the Sections. Thus the officers will have measurable control of the material to be submitted both as to its amount and quality.

2. With reference to the reporting of the proceedings. We deem this an important matter. No just estimate can be made of the work done in any given Section unless it is properly reported. We have reached the point now when such reporting is perfectly feasible. The present receipts of the treasury will safely permit the necessary expenditure. We have carefully considered the cost and find that expert medical reporters can be secured by a single contract for the full reporting of the eleven Sections, in typewritten copy, for from eight hundred to one thousand dollars per year.

An annual appropriation of one thousand dollars, which the present income of the treasury will fully warrant, will secure the full and satisfactory reporting of our entire proceedings.

3. The publication of the papers presented in the Sections. These should be referred to the careful supervision of men specially qualified for their work by reason of their familiarity with the subjects to be considered. We believe the best interests of the Association will be promoted by the selection of one member from each Section who shall be charged with the duty of preparing the papers and discussions of his Section for publication, and that suitable recognition for such services should be made, in such manner as the Association may deem advisable.

No editor-in-chief, nor supervising editor, is alone competent to this work, and once the supervision is given into the hands of those who are experts in their specialties, the "Original" department may become the crowning feature of our JOURNAL.

In the next issue we purpose to consider the question of the increase of our membership, and in that connection to suggest the propriety of appointing, at a suitable time, an able committee which shall consider these various subjects, and at a subsequent meeting, recommend to the Association such modifications of our present plans as may be deemed desirable.

LAST WINTER'S EMERGENCY IN PARIS.

The efficient measures adopted in Paris for the relief of the poor and starving, during the terrible cold of last January, command our highest admiration. The statistics, showing the number of lodgings and meals provided, have been cited with wonderment throughout Europe. For celerity of action and unstinted relief to the suffering the Municipal Council have left a record that must prove most stimulating to other cities when they shall have been brought face to face with a like trying emergency of cold and want.

Much want occurred in unexpected quarters because so many people were thrown out of employment by the extreme cold and they could not get the money wherewith to pay their rent. Many such were compelled to leave their homes and live in the streets, for a time at least. This strange emergency was met by the prompt establishment of eighty or more "brasseros" or great open fires in grates in the public places, so that many were there cheered and revived when weakened by the cold. Temporary refuges and special

shelters for women were organized in art galleries and gymnasia so as to accommodate many hundreds, giving both food and sleeping places. All this was done by the authorities without hesitation or red-tape. The maximum of these lodgings taken up on any one day was 4,500. The beds consisted of a mattress of straw and a military rug, or robe, provided by the War Department. Soup was served out morning, noon and night. As many as 24,000 soup-portion were prepared in a single day. It is calculated that the soup cost about three cents per plate. It was made of beans, peas, lentils, salt and lard, bones and fresh vegetables being exorbitantly high priced during the "cold snap." The lard was found to make a fair substitute for soup-meat. Soup of this kind was still being given out at the Paris refuges after the month of March had opened. The heartiness, catholicity of charity, and even hospitable spirit with which this proffer of relief was extended made it easy for those in want to accept of it. At first no inquiry was made of any applicant, but subsequently, when the rigor of the cold had moderated, the personal descriptive papers were required to be shown. Perhaps the most active man in all this charitable work was Dr. Paul Brousse, a vice-president of the Municipal Council, and physician. It was in part, at least, due to his personal representations to the authorities that some of the measures of relief were so rapidly undertaken; and he thus became the willing means by which much suffering, sickness, starvation and mortality were prevented. Not the least remarkable feature in strange situations was the celerity of action on the part of public officials, who for the time being became a unit in the disregard of precedent, red-tape and every other ordinary occasion for delay.

If the poor famishing Brules and Ogallalas, in the West, could for a short time only have the services of Dr. Paul Brousse, it would be a god-send to the country.

SPLENIC LEUCOCYTHEMIA.

DR. H. TOULMIN has described in the *Johns Hopkins Hospital Bulletin* a well-marked case of this disease, in which the microscopic blood-conditions were examined with more than usual minuteness. The patient was a colored waiter twenty-three years old. He gave a history of malarial

infection, dating back about two years; and had been suffering from swelling of the abdomen and legs from six to nine months. Among other symptoms he had had were epistaxis, a slight diarrhoea and incontinence of urine; priapism, so often observed in leucocythemia, was denied as having existed. The splenic "lump in his stomach" was first noticed by the patient about nine months before, when it would seem to have attained its present enormous size quite rapidly. It was prominent in the left hypochondrium and epigastrium, and occasioned a girth of 36 inches at umbilicus. The lump was a firm, solid and movable mass, occupying the left zone, reaching to the level of the anterior superior spine, to nearly three inches from the pubic bone and to three and a half inches to the right of the median line at the umbilicus. The edge of the swollen spleen could best be palpated in the right inguinal region. No notch could be felt. Posterior dullness on percussion extended from the lower border of the seventh rib for sixteen inches. There was no pulsation; no murmur could be heard; the superficial veins showed no enlargement; no engorgement of the lymph-glands, and no tenderness over the bones or enlargement of their extremities were found. The examination of the blood showed the proportion of white corpuscles to be as one to four, to the reds; reds were 2,008,000; hæmaglobin 30 per cent. Two weeks later, there were reds 2,700,000; proportion of whites to reds 1 to 4.48; total of Fowler's solution taken minims cc.; hæmaglobin not stated. One month after last entry, there were reds 3,430,000; proportion of whites to reds 1 to 18.8; total of Fowler's solution minims cccxx; hæmaglobin 51 per cent. As indicated in the above, the patient was put on Fowler's solution, beginning with three minims thrice daily, and increased to six minims. Under this treatment the œdema was reduced, and some of the other symptoms were mollified; but the splenic enlargement remained and was practically unchanged. The general condition of the patient is otherwise favorable, and the man reports to be feeling well. An examination of the cell-elements, made according to Ehrlich's method, show the blood to contain some in deficient quantity, such as lymphocytes 4 per cent.; polynuclear neutrophiles 50 per cent.; mononuclear transition forms 5 per cent.; while others are in excess,

such as eosinophiles 5 per cent., and myelocytes mononuclear neutrophiles 30 per cent. Not the least remarkable feature in the case is the excellent general condition that has been sustained; he states that he has never before weighed more than 165 pounds, while at present his weight is ten pounds above that record.

EDITORIAL NOTES.

THE PRELIMINARY TRAINING OF RAILWAY EMPLOYÉS.—In view of the very large number of accidents, resulting either fatally, or in the maiming of the unfortunate ones for life, it is proposed to establish schools of training at favorable railway points. In the aggregate the number—2,000 killed, and 20,000 injured in 1890—of sufferers is great, and the utmost means of prevention should be taken. It is true that carelessness is responsible for a goodly proportion of the accidents, and it is this very factor which will be largely overcome by a proper drilling, and a due presentation of consequences.

A NEW DISEASE.—Two English physicians—Dr. Hale White and Mr. Golding-Bird—have recently described an affection to which they give the name "Idioglossia." It appears that the patients hear well, and express themselves in articulate sounds, but such sounds are unlike those of any known language. The patients really have a language entirely of their own, in which there does not seem to be any confusion. *i. e.*, the sounds given forth have an intelligent application, and the same sound always has the same meaning. The discussion before the Royal Medical and Chirurgical Society was varied, some of the members contending that the so-called language of those affected was but a modification of the English tongue, and was to be accounted for by a lack of development in that particular direction.

A LITERARY PHYSICIAN.—Notwithstanding the almost constant application required of a physician in the active pursuit of his profession, yet there are men—we have them in this country—who find, or make, the opportunity of adding literary laurels to the honors achieved in medicine.

Dr. William Stricker, of Frankfort-on-the-Main, has recently passed away, leaving behind enduring works, of which the following is a partial list: "History of Medicine in Frankfort;" "The Lives of Soemmering, Neff and Stiebel;" "Ett-

ner's Medical Novels;" "The Cure of the Sick in the Wars of the Past;" "Taylor, Ludwig Hoernigk, Burgrave, Haller, Zimmerman;" "The Mortality of Children;" "Suicide;" "Marriages between Blood Relations;" "Medical Statistics;" "Hermaphroditism;" "Hairy Men;" "Small-pox;" "Vaccination;" "Labial Cancer;" "The Effects of Lightning on the Human Organism;" "History of Frankfort;" "Life of Goethe," etc.

A CASE OF ACROMEGALY.—Dr. Joseph Redmond has recently reported to the Irish Royal Academy of Medicine a case of acromegaly, believed to have been the first hitherto reported from Ireland. According to the *British Medical Journal* the attack dates from December, 1889, during the prevalence of the influenza. The patient, a female of 19 years, was admitted to the hospital in July last. The first symptoms that attracted her attention were the changes in her hands and feet, which became swollen, sore and tender to the touch. The hands were large, fingers thick and bulbous, with nails somewhat convex; the back of hands became œdematous, but did not pit on pressure. There was marked increase in the size of the carpal ends of both radius and ulna. The knees were enlarged, as well as the legs and ankles. The ankle-joints contained some effusion. The feet were larger and thicker than normal; the toes were thicker and bulbous. The dorsum of the feet was œdematous. Urine normal. The thyroid gland appeared to be absent, and no evidence of the persistence of the thymus could be obtained. Pulse average was 100; temperature 101.6°; respirations 24. The patient has at times complained of lumbar pains, and has had occasional attacks of diarrhœa.

DEPOPULATION FROM DISEASE.—Official reports go to show that the native population of Alaska is fast disappearing, mainly from the severe ravages of syphilis, tuberculosis and small-pox. Medical measures are unknown, yet if there was some appreciation of the advantages of prevention and treatment there appears to be no opportunity by which aid could be given. The plight of these unfortunates is certainly a sorry one, and the possibilities for the medical missionary are great. Some attention, whether governmental, or through the operation of the organ-

ized charitable associations, should be directed to this state of things prevailing upon American soil.

A VERY COMMENDABLE FASHION.—Occasionally Fashion—so-called—has the credit of leading the susceptible mind into channels where Health and Vigor follow. This is the case—this is the leading—at present in regard to hot milk as a popular beverage. If only the temperance disciples could fully awake to the golden opportunity this "fad" opens!

Hot milk is a wonderful food and stimulant. It combines these two virtues most happily, more so, probably, than any other one substance, or combination of substances. National degeneracy need hardly be feared from the universal consumption of hot milk as a constant drink. We can see but one danger in this direction, and that we believe will be fully overcome by having the temperature of the milk, in all cases, carried to the boiling point.

EPIDEMIC INFLUENZA IN AFRICA AND ASIA.—Letters from the Congo Free State mention the occurrence, in October last, of an extension to those parts of an epidemic sickness that bears a very close resemblance to the "Russian influenza." Nearly everybody has had "a cold," while some have been very ill. The season there has been unusually cold in the upland regions, two and three hundred miles back from the coast.

A letter in *The Lancet*, also, states that at Gilgit, Kashmir, in December, there had been an epidemic, supposed to have been taken there by a party of Moslem priests from a place 200 miles farther west, where the influenza had already been prevalent. These mountain valleys, about 5000 feet above the sea, called the Hindu Khush valleys, have hitherto been exempt from the influenza, although it had existed in India earlier in the year 1890. The invasion seemed to approach from the west rather than from the south, although the avenues of communication, in the latter direction, were much more accessible.

THE INTERVIEWER IN MEDICINE.—Some of our New York brethren in open rebellion against the American Medical Association, held an experience meeting a few weeks ago, to which some how the ubiquitous reporter also came, presumably for the benefit of those who do not take the journals. There was a debate upon the inter-

views as conducted by the secular press, faintly apologetic but mainly mock-heroic in tone with which nearly all (lay and professional) regaled themselves at their morning breakfast. With a single exception, the speakers who were sticklers for the dignity of the profession were either silent or un-reported. We need not remind our brethren of goodly Gotham, who are so strenuous about enlightening the public, that there is an oft quoted phrase about barking with bounds and running with the hare. There also comes to us the story of the vain-glorious veteran, of whom some little Wilhelmina, "with wonder-waiting eyes" asked, "Grand-pa didn't you have anybody to help you."

MEDICAL ITEMS.

DISSECTION MATERIAL IN NEW YORK.—A bill to meet the wants of post graduate instruction in surgical anatomy at the two schools in New York City has been put upon its passage. The under graduates' schools have hitherto been able to absorb all the material allowed by law to be distributed to the colleges. The new arrangement will, if it passes the legislature, enable the post-graduates to come in for a *pro rata* share.

CRUELTY OF A NURSE PUNISHED.—A recent conviction in New York has resulted in sending up to Sing Sing Prison a former Bellevue Hospital nurse, who struck a blow at a delirium tremens patient, who spat upon the nurse; the patient was in a strait-jacket at the time. The conviction was for assault in the second degree and the term of imprisonment will be two years and eight months.

A TORNADO MEMORIAL HOSPITAL.—The citizens of Louisville, on March 27, commemorated the cyclone of last year by meeting and by taking up collections for the establishment of a Children's Hospital, to be a memorial of the destructive tornado. It is reported that \$30,000 have already been promised for this unusual project to link a great public calamity with an enduring monument of charity, and thus convert it into a blessing in disguise.

INFLUENZA IN CENTRAL AFRICA.—A recent number of the *Lancet* publishes a letter, dated October 11, 1890, from the neighborhood of Lake Nyasa, Central Africa, by which it appears that epidemic influenza had just reached that distant

point. It had been very severe and a number of deaths among the natives had resulted from it or its consequences; most of the Europeans at Blantyre, a Scottish mission station near the Shiré River, had been attacked by it in a more or less severe form.

TOBACCO AND ORGANIC LESION OF THE HEART.—In connection with the discussion which occurred at the New York Academy of Medicine at its stated meeting of Dec. 18, 1890, (as chronicled in the *Medical Record* of Jan 17, 1891), relative to the influence of tobacco upon the system, the President, Dr. A. L. Loomis, thought that when tobacco poisoning reached a point where it produced disturbance of the heart there was something more than functional disturbance; there was a change either in the connective tissue or of the muscular fibres of the heart. Such hearts did not bear ether nor cocaine. He impressed the fact that the heart condition was not functional; it was organic.

Dr. A. Jacobi having elicited from the President the opinion that in such cases there was never, as far as his observation had gone, entire recovery from the heart trouble, said that he could not agree with him. He knew persons who had had functional disturbance of the heart from tobacco-poisoning recover entirely after the use of tobacco had been discontinued. That was a hope which he thought we should hold out to our patients, unless it could be shown that the lesion causing the disturbance was of a nature which did not admit of entire recovery.

The President thought Dr. Jacobi had in mind cases of disturbance of the stomach from use of tobacco, which caused reflex irritability of the heart.

Dr. Jacobi remarked that the President seemed to know his mistakes better than he knew them himself. He did not believe that he had made a mistake, although he thought there was room for diversity of opinion. He would be very sorry to have patients get the idea that their condition was an organic change in the heart which could not be remedied.

Dr. Andrews mentioned a case in which the man was obliged, twenty-five years ago, to give up tobacco on account of disturbance of the heart, and he remained well to-day at 76.

TOPICS OF THE WEEK.

OFFICIAL REPORT ON THE RESULTS OF KOCH'S TREATMENT IN PRUSSIA.

We surrender the space usually assigned to the consideration of current medical topics, this week, that we may present to the readers of THE JOURNAL a very complete *résumé* of the results thus far obtained in Prussia, in connection with the use of tuberculin in the treatment of tuberculous diseases. From the voluminous report published as a supplement to the *Klinisches Jahrbuch der British Medical Journal* of March 14, presents the following valuable abstract, which we publish entire:

The official report of the results of Koch's treatment of tuberculosis, as observed in the University clinics and "polikliniks," and other public institutions of Prussia, has just been issued in the form of a supplement to the *Klinisches Jahrbuch*, a publication which owes its existence to Cultus Minister von Gossler. The editor of the volume is Professor Albert Guttstadt, Lecturer on Medical Statistics in the University of Berlin. It includes 55 reports, of which 43 are from the University clinics and "polikliniks," 2 from non-clinical departments of the Charité Hospital, 2 from the Moabit City Hospital, and 8 from pathologico-anatomical institutes of universities. The period to which the reports refer comprises, as a rule, the eight weeks from the beginning of November to the end of December, 1890; in some few cases, however, it goes down to the middle of January, 1891. The reports of Professor Fränzel and Dr. R. Köhler begin from September 12 and October 11 respectively. The total number of patients injected during the period covered by the reports was 2,172, the total number of injections being more than 17,500. The greatest number of injections in any one case was 54. This patient was under the care of Dr. Paul Guttmann, suffering from very advanced pulmonary phthisis, and he received in all 3,345 grams of the mother liquor. He is now in a relatively favorable condition, but there is no appreciable change in the objective symptoms. The largest quantity of tuberculin administered in any one case was 3,826 grams. This patient (a man with pulmonary phthisis, under the care of Professor Fränzel) received in all 43 injections. In this case remarkable improvement in the physical signs and in the general bodily condition followed the treatment, and was maintained when last heard of (in February).

The volume contains reports from Professors Leyden, Gerhardt, Senator, Fränzel, Bardeleben (with Dr. A. Koehler), Olshausen, Jolly, Henoch (with Dr. Goerne), Lewin, Schweninger, Schweigger, Lucae, E. von Bergmann, B. Fränkel, and R. Virchow, and Drs. R. Köhler and Westphal, of the University of Berlin; Professors F. Schultze, Trendelenburg, Doutrelepoint, Walb, Finkler, and Koester, of Bonn; Professors Biermer, Mikulicz, Fritsch, Neisser, and Ponick, of Breslau; Professors Ebstein, König (with Dr. Hildebrand), and Orth, of Göttingen; Professors Mosler and Strübing (with Dr. Peiper), and Helferich, of Griefswald; Professors Weber, von Bramann, Schwartz, and Ackermann, of Halle; Profes-

sors Quincke, Edlefsen, von Esmarch, and F. Petersen, of Kiel; Professors Lichtheim, J. Schreiber, Braun, von Hippel, and Neumann, of Königsberg; Professors Maunkopf, Rumpf, Küster, Barth and Marchand, of Marburg; besides supplementary reports from Professor Julius Wolff, of the Berlin Orthopædic Poliklinik, Professor A. Heller, of the Pathological Institute at Kiel, and Dr. Paul Guttmann and Professor Sonnenburg, of the Moabit Hospital, Berlin. Professor Koch's two papers on his remedy are published in an appendix. Finally, there is an elaborate analysis of the reports with tabular statement of the clinical details, number and doses of injections, and results in most of the cases, by Professor Guttstadt.

DIAGNOSTIC VALUE OF TUBERCULIN.

Internal Tuberculosis.—Leyden looks upon tuberculin as of essential service in confirming the diagnosis of tuberculous disease, but in the absence of definite symptoms would not rely on it alone for that purpose. Gerhardt thinks it is not absolutely to be depended on, inasmuch as cases have occurred in which, though tubercle bacilli were undoubtedly present, the injection caused no reaction. It may, however, be useful for the differentiation of tubercle from syphilis in the larynx and lung. Schultze thinks it, within certain limits, a reagent for the detection of tubercle. Biermer expresses himself with some reserve, as he has met with two cases of certain tuberculosis with bacilli in the sputum in which continued injections produced neither general nor local reaction. Ebstein thinks the detective action of the fluid uncertain; This opinion is shared by Mosler, Strübing and Peiper, who, nevertheless, think tuberculin may help to show whether previously existing tubercle is cured or not. Weber says it is not a sure diagnostic agent for internal tuberculosis, and does not give certain results in doubtful cases; it is more useful in external disease. Quincke is at present unable to conclude that in all cases in which the fluid causes reaction there are latent foci of tuberculosis. Finkler and Schreiber place more reliance upon it, and Rumpf thinks it of service in doubtful cases. P. Guttmann speaks in the tone of an ardent believer. In pregnant women Olshausen says tuberculin has failed to produce any reaction when the existence of phthisis was certain. Fritsch thinks the fluid is of high diagnostic value in the differentiation of tubercle from cancer.

External Tuberculosis.—Bardeleben and A. Köhler admit that tuberculin occasionally fails to produce reaction in cases of external tuberculosis; they think this may possibly be accounted for by individual idiosyncrasy or by slight differences in the fluid itself. Von Bergmann thinks it is a valuable means of differentiating tubercle from syphilis and cancer; Trendelenberg considers it reliable except in tubercle of the testis; Mikulicz places confidence in it; König and Hildebrand do not value it highly; Helferich thinks it an important aid to diagnosis; von Bramann says it is "apparently" a *suro* reagent for tubercle; von Esmarch also thinks highly of it in lupus and in bone and joint disease; von Braun and Küster think it extremely useful, though not infallible; R. Köhler and Westphal look upon it as superior to all

known aids to differential diagnosis; Lewin considers it useful; Dautrepoint and Neisser think it of high diagnostic value; von Hippel has found it of service in two cases of doubtful eye disease.

THERAPEUTIC RESULTS.

Commencing Pulmonary Phthisis.—Leyden treated 9 cases of commencing pulmonary phthisis, but no statistics are given as to results. Gerhardt treated 15 cases, of which 4 were discharged improved and 11 are still under treatment; of the latter 3 are said to be materially improved, 1 is improved, while in 7 there is no change. Senator reports 39 cases, of which 10 have been discharged and 29 are still under treatment; of those belonging to the former category, 3 were materially improved, 3 were improved, and 4 were *in statu quo*. Of those still under treatment, 2 are greatly improved, 3 improved, 20 are unchanged, and 4 have been made worse. Schultze has treated 9, of which 1 has been discharged unrelieved, while of the 8 still remaining under treatment, 2 are materially improved, 2 improved, and 4 unrelieved. Biermer has had 12 cases, of which 2 have been discharged unrelieved, while of the remaining 10, improvement is recorded in 6 and no improvement in 4. Ebstein reports 3 cases, of which 1 was discharged unrelieved, while of the 2 others, 1 is not improved and 1 is described as worse than before the injections were begun. Of 7 cases treated by Mosler, 2 have been discharged materially improved, 1 improved, and 2 unrelieved; of the 2 still under treatment, both are improved. Of 9 cases still under treatment by Weber, 3 are materially improved and 6 are improved. Quincke reports 10 cases, of which 2 have been discharged improved, while the 8 still under treatment show no change. Lichtheim has 9 cases under treatment, of which 2 are greatly improved, 4 are improved, and 3 are unchanged. Mannkopf has 9 cases under treatment, of which 1 is greatly improved, 2 are improved, and 6 are unrelieved. Finkler has had 10 cases, of which 4 were discharged cured and 3 greatly improved; the 3 remaining under treatment were all improved. Edliefen has 2 cases under treatment, both of which are materially improved. Schreiber reports 12 cases, 1 of which was discharged cured and 2 unrelieved; of the 9 still under treatment, 2 are greatly improved, 1 is improved, and 6 are unchanged. Of 19 cases under Rumpf's treatment, 13 are greatly improved, 5 are improved, and 1 shows no change. Of 3 cases under Fränzel's care, 1 is greatly improved and the other 2 show no change. Of 54 cases treated by P. Guttmann, 4 have been discharged cured, 8 greatly improved, 1 improved, and 1 *in statu quo*. Of the 40 cases still under treatment, 21 are greatly improved, 10 are improved, and 9 are unchanged. Neisser reports 2 cases, both improved. Henoch has 5 still under treatment, of which 1 is improved and 4 unchanged. B. Fränkel has 4, all of which show great improvement.

Moderately Advanced Pulmonary Phthisis.—Leyden has had 23 cases, of which no particulars are forthcoming. Gerhardt has had 34, of which 2 have been discharged unrelieved, 2 have died, and of the 30 still under treatment 3 are materially improved, 1 improved, and 25 unchanged. Senator has had 32 cases, of which 1 has

been discharged greatly improved, 6 improved, and 14 unrelieved, while 1 has died; of the 10 cases still under treatment 1 is greatly improved, 3 are improved, and 6 show no change or have been made worse. Schultze has 26 under his care, of which 2 are greatly improved, 4 improved, and 20 unrelieved. Biermer reports 17 cases, of which 1 was discharged unrelieved, 1 died, and of the remaining 15, 5 are improved, and 10 show no change. Ebstein records 18 cases, of which 6 have been discharged unrelieved, and 12 are still under treatment without showing any improvement. Mosler has had 25 cases, of which 4 have been discharged much improved, 4 improved, and 14 unrelieved; of the 3 still under treatment all are much improved. Of 13 cases under Weber's care, 2 are much improved, 4 improved, and 7 unrelieved. Of 21 under Quincke not one shows any improvement. Of 16 under Lichtheim, 1 has died; and of the 15 still under treatment, 9 are improved and 6 unchanged. Of 13 under Mannkopf, 1 is greatly improved, 5 are improved, and 7 are unchanged. Of 27 cases reported by Finkler, 2 have been discharged materially improved, 5 improved, and 13 unrelieved; of the 7 still under treatment, 2 are improved, and 5 show no change. Of 4 cases under Edliefen, 1 has been discharged much improved, and 1 has died; of the 2 still under treatment, 1 is improved, the other not. Of 11 cases treated by Schreiber, 1 has been discharged improved, and 4 unrelieved; of the remaining 6, there is material improvement in 1, while 5 show no change. Of 20 cases treated by Rumpf, 3 have been discharged unrelieved, and 1 has died; of the 16 still under treatment, 6 are much improved and 10 *in statu quo*. Of 16 under Fränzel, 3 have been discharged improved, and 1 has died; of the remainder, 4 are greatly improved, 2 are improved, and 7 are unchanged. Of 112 cases under P. Guttmann, 16 have been discharged much improved, 4 improved, and 5 unchanged; of the 87 still under treatment, 14 are greatly improved, and 3 unchanged. Henoch has had 1 case, which was discharged unrelieved or rather worse than before. B. Fränkel has had 14, of which 1 has been discharged cured; the 13 still under treatment are all greatly improved. Lewin has had one case, which was discharged unrelieved.

Very Advanced Pulmonary Phthisis.—Leyden has had 20 cases, of which 4 have died; as to the remaining 16 no details are furnished. Gerhardt has had 8, of which 1 has died, and 7 are still under treatment without showing any improvement. Senator has had 8, with 3 deaths, the remaining 3 being unrelieved. Schultze reports 14, in none of which has there been any improvement; Biermer 7, with 1 death and 6 unrelieved; Ebstein 6, of which 2 have been discharged unrelieved, while 4, which are still under treatment, show no improvement; Mosler 28, of which 3 have been discharged greatly benefited, 7 improved, and 14 unrelieved, while of the 5 still under treatment 1 is improved and 4 unchanged; Weber 22, of which 2 have died, 2 are improved, and 18 unchanged; Quincke 5, of which 1 is improved and 4 not; Lichtheim 9, with one death, 4 improved, and 4 unrelieved; Mannkopf's, of which 1 is improved and 17 unchanged; Finkler 32, of which 1 have been discharged improved, and 11 unrelieved, and 2 have died, while of the remaining 19, 2

are improved and 14 *in statu quo*; Ellefsen 3, all unchanged; Schreiber 6, of which 1 has been discharged improved, 3 unrelieved, and 1 has died, while the 1 still under treatment shows no improvement; Rumpf 7, of which 1 has been discharged unrelieved, while of the 6 still under treatment 2 are improved and 4 *in statu quo*; Fränzel 17, of which 1 has been discharged improved, 1 unrelieved, 4 have died, whilst of the 11 still under treatment, 1 is greatly improved, 3 are improved, and 7 are unchanged; P. Guttman 30, of which 5 have been discharged unrelieved and 8 have died, while of the 17 still under treatment none show any improvement; Sonnenburg 7, of which 3 are greatly improved, 3 are improved, and 1 is unrelieved; Olshausen 3, of which 2 have been discharged unrelieved, while 1 is *in statu quo*; Henoch 1, discharged unrelieved; and B. Fränkel 5, with 1 death, 1 improved, and 3 unrelieved.

On the whole Leyden is fairly satisfied with the results so far, while Senator thinks them better than could have been produced by any other treatment; Schultze is not enthusiastic; Ebstein is inclined to be pessimistic; Biermer states that in 3 cases the tuberculous process made distinct headway during treatment; Mosler, Strübing, Peiper, Weber, Finkler, and Schreiber all speak with reserve; P. Guttman claims decided "improvement" in 38 per cent. of all his cases (164), and in 81 per cent. of the "incipient" cases taken alone.

Effect of Treatment on Symptoms in Phthisis.—1. Body weight: Of 61 cases under Gerhardt, 22 have gained weight, 17 remain as before, and 22 have lost. The gain ranged from $\frac{1}{2}$ to 5 kilos., the loss from $\frac{1}{2}$ to 5½ kilos. In one of the Senator's cases 4.4 kilos. were gained in a week, and on several occasions there was an increase from $1\frac{1}{2}$ to 2 kilos. in the same space of time. Eight patients in a very advanced stage of phthisis, with cavities, chronic diarrhoea, etc., gained weight, in some cases as much as 2½ kilos. Biermer found increase in 11 cases, the average gained being from 2 lbs. to 3 lbs., and in one case as much as 10 lbs. In 17 cases there was progressive loss of weight to the extent of 1 lb. to 6 lbs.; in the other cases there was neither loss nor gain. Weber noted increase in 16, and loss in 28, while in 12 it remains stationary. P. Guttman says the weight increased in a large number of cases under his care, the maximum gain being 7½ kilos. 2. Expectoration: Gerhardt says expectoration mostly increased at first, in 5 cases it became bloodstained. Afterwards it gradually decreased, and became more mucous. In several cases the bacilli seemed to diminish at first; in particularly favorable cases they disappeared from the sputum. Senator found that the bacilli diminished in favorable cases, but in no instance disappeared altogether. Ebstein has seen no improvement either in the quantity or the quality of the sputum, and no diminution of bacilli. Mosler on several occasions noticed that the expectoration was bloodstained, but he did not see actual hæmoptysis. Weber says cough was improved in 14 cases, increased in 15, and remained *in statu quo* in the rest. The expectoration was diminished in 18, increased in 12, and unchanged in the remainder. Lichtheim says that in almost all cases after the subsidence of the reac-

tion both cough and expectoration were lessened. In one case expectoration and the appearance of bacilli followed the commencement of the injection, and ceased on their discontinuance. Mannkopf noticed little or no

change in the quantity or quality of the expectoration. 3. Respiration: Gerhardt says that vital capacity increased in 5 out of 10 cases. 4. Physical signs: Gerhardt says that in many cases there was diminution of dullness and *râles*. Senator noticed in some favorable cases a complete disappearance of catarrhal signs and *râles*. Neither Elstein nor Mannkopf observed any particular change in the physical signs. Fränzel says that after treatment had been continued for a certain time the *râles* almost disappeared in some cases. 5. Night sweats: Senator records the cessation of night sweats even in cases where before the treatment they had been considerable in amount. Weber says that in 11 cases the night-sweats diminished, while in 3 they increased. Lichtheim, Mannkopf, and Fränzel also say the injections had a good effect on night-sweats. 6. General condition: Gerhardt says that three patients felt so well that they insisted on leaving the hospital, though the physical signs showed that they were not cured. In 10 cases the treatment had to be discontinued by reason of weakness, persistent fever, or progressive loss of weight. Senator says the treatment had a favorable effect on the subjective feelings of a large number of patients; they looked better, and were stronger and more cheerful. Biermer, on the other hand, found that many patients complained that the treatment made them feel weaker and lower. Mosler notes an improvement in the appearance of patients. Weber says that the general condition became worse in 22 cases, while 33 patients expressed themselves as satisfied with the effects of the remedy.

Other Tuberculous Diseases.—The general results of the treatment in laryngeal phthisis, lupus, and other forms of tuberculous diseases will be seen in the table here appended, which is literally translated from pages 904, 905.

SOCIETY PROCEEDINGS.

St. Louis Medical Society.

Stated Meeting, Saturday, February 28, 1891.

THE PRESIDENT, L. BREMER, M.D., IN THE CHAIR.

[Abstracted for THE JOURNAL.]

TUBERCULOSIS (?) OF THE LIVER.

DR. GALE presented an abscessed portion of a liver taken from a boy 11 years old. An abscess had formed over the liver two years ago, and latterly a tumor had developed in the same situation. Syphiloma was excluded. Upon operating a tumor involving one-third of the right lobe was found, and which was removed. The temperature, which had previously been 101° constantly, regained the normal point after the operation, and the case (twelve days after) promised a good recovery.

Discussion was postponed pending a microscopical examination of the specimen.

ACUTE OTITIS MEDIA.

DR. BARCLAY reported a case of this disease where quinine had been ordered in large doses, with the effect of greatly increasing the patient's distress, and where relief was found by the almost constant application of cold water to the ear. The patient had himself applied the cold water from a well for two nights and one day.

DR. BREMER mentioned a case of death from probable meningoccephalitis as the outcome of a too severe syringing of the ear; and a case, also, of the same inflammation from a too severe syringing of the nose. He did not believe it a good or safe practice to inject a forcible stream into these cavities.

DR. WILLIAMS thought the President accused the syringe unjustly. He believed the ear syringe had been made to answer for a great many results it was in no wise accountable for. He had certainly used the syringe a great deal, yet had never seen encephalitis induced.

DR. F. J. LUTZ agreed with Dr. Williams, still an observation of two recent cases wherein meningitis followed closely upon the use of ear and nasal syringes, led him to believe that there might at times be danger in the unskilful and untimely use of these measures.

DR. LOEB did not think harm followed the reasonable use of the douche. Exaggerated cases, doubtless, there were. He advocated the spray instead of the douche.

DR. FUNKHOUSER reported an interesting case of inflammation of the ear, extending to the meninges and finally resulting in death, and in which the syringe was not used.

DR. GLASGOW reported a case very similar to that of Dr. Funkhouser, and in which a syringe had not been used.

DR. BARCLAY remarked that the ear syringe, like almost all other instruments of value in the physician's hands, might be used in such manner, and at such times, as to cause harm. Discretion and judgment were highly necessary. He mentioned a case where syringing had been resorted to three times daily for three months, for an abscess, yet when it was discontinued the abscess healed completely in three days. He believed that authorities discarded the syringe more and more as their experience became extended.

DR. BREMER said that he recognized the different results which would occur from the use of the instrument in the hands of the intelligent experienced, and the thoughtless inexperienced.

HYPNOTIZING A MEDICAL PROCEDURE.—In a recent discussion of the question: Should a person, who, not being a member of the medical profession, performs hypnotic experiments on another, be prosecuted for illegal practice of medicine? The Conference of Paris Advocates decided in the affirmative.

FOREIGN CORRESPONDENCE.

LETTER FROM LONDON.

(FROM OUR OWN CORRESPONDENT.)

Sir James Crichton Brown on "Brain Rest"—B Naphthol and Salicylate of Bismuth as a Disinfectant in the Internal Treatment of Typhoid Fever—Results of Treatment with Dr. Koch's "Tuberculin"—The Consumption of Ether by the Irish—Miscellaneous Gleanings.

Sir James Crichton Brown, in his course of lectures recently delivered upon the subject of "Brain Rest," said that ordinary sleep grows deeper for the first hour and a half and then steadily diminishes until the slumberer awakens. Dr. Brown pleaded for eight hours for actively working brains, though ascetic notions have led many people to shorten the time, with the result that in certain cases it has been proved that the amount of sleep may be considerably reduced without injury. Literary men were apt to starve the brain in the matter of sleep, but some, nevertheless, had got on pretty well in spite of insomnia. Carlyle and Rossetti furnished instances. Dr. Brown quoted a letter from his friend Dr. Tyndall, who said: "For four weeks I have never had a single second of sleep, and during those nights I walked thousands of times round my room to no purpose. What astonishes me above all" (he adds) "is notwithstanding my nights' weariness my brain power does not appear to be sensibly impaired. After two or three hours' sleep I feel my brain as strong and clear as it ever was at any period of my life." It is, in Sir J. Crichton Brown's opinion, impossible to doubt that nutrition and repair must have gone on in the brain during periods of sleeplessness. The brain in short must, as he expressed it, "have learnt the trick of the heart and gone to sleep during the beats, or it must have slept in centres which were not active at the same time."

During the recent prevalence of typhoid fever various agents have been brought forward as disinfectants in the internal treatment of the disease. Several physicians consider naphthol to be superior to any other. There appears to be two kinds of naphthol, one which is more soluble and less toxic, but more irritant, is called A naphthol, the other less soluble, more toxic, but less irritant, is called B naphthol. It is to the latter that preference is given, it being associated with salicylate of bismuth, both being given in the form of powders or granules, in such a manner that the patient takes daily from fifteen to thirty grains of naphthol.

The news has arrived that the official reports from all the Prussian clinics and pathological institutes on the results of treatment with Dr. Koch's "tuberculin" have been published by the Ministry for Public Instruction. It appears that

the results were much better than was believed. From the middle of November to the end of December 2,172 persons received injections, the number of injections being more than 17,500. Of these patients 932 had tuberculosis of the lungs, 120 tuberculosis of other internal organs, and 700 external tuberculosis. Of those suffering from tuberculosis of the internal organs 13 were cured, 171 considerably improved, 194 improved, and 46 died. Of 708 patients suffering with external tuberculosis 15 were cured, 148 were considerably better, 237 better, and nine died.

There has lately been a great outcry concerning the consumption of ether by the Irish who have chosen it as an intoxicant, and in the House of Commons, in answer to a question by Dr. Tanner, Mr. Balfour said: "As stated by my right honorable friend the Chancellor of the Exchequer, in reply to a question addressed to him on December 1st, ether has been scheduled and it can now only be sold by qualified chemists or druggists as a poison." The statement laid before the executive government by Mr. Thomas Ledlie affords some idea as to the alarming proportions the habit had assumed. Mr. Ledlie calculates that seventeen thousand gallons of impure ether of the vilest form is annually consumed by the people in the districts situated in the counties of Derry and Tyrone, as well as parts of Armagh, Monaghan and Fermanagh, no fewer than 100,000 people spread over an infected area of 190,000 acres indulge in this baneful habit. He suggests six ways of getting rid of what he considers a baneful practice, the chief of which may be summarized as follows: The introduction of naphtha into the preparation of all ether, save that used purely for medicinal purposes, which would give it nauseating odor and taste, the reimposition of a prohibitive tax, and the making of the practice illegal and placing it upon the criminal code, as well as making the sale of ether illegal by all persons save chemists, and by this class of persons only for *bona fide* medicinal or commercial purposes.

At the Westminster Hospital there has recently been a death by asphyxia caused by exophthalmic goitre. The patient, a girl aged 20, had been under medical care for twelve months. In spite of treatment the goitre slowly increased until there were attacks of dyspnoea. Upon admission to the hospital asphyxia became imminent, and Mr. Spencer opened the trachea through the upper part of the tumor. The gland substance bulged greatly when the capsule was divided, and there was a large amount of hemorrhage. Upon opening the trachea no improvement in the breathing took place, nor was there upon the introduction of an ordinary tracheotomy tube. A vulcanite tube was then passed for four inches down the trachea, when air entered freely. For a time the dyspnoea was entirely relieved, but during the evening mucus collected below the

tube, this the patient was unable to cough up, and she died asphyxiated. The operator considered that this termination of such a case was extremely rare. Mr. Spencer thinks that some recent operations by which a cure had resulted after the removal of a great portion of the gland connected the pathology of the disease closely with the thyroid gland.

The Senate of the University of London has received communications from the Royal College of Physicians and Royal College of Surgeons to the effect that both these institutions had given their complete adherence to the scheme proposed for granting a medical degree to London students after going through a prescribed course of education and passing the required examination by a competent board, formed by representatives from the University and the two Royal Colleges. This will be an immense boon to the students of the London medical schools, who have hitherto been obliged to go in search of degrees bestowed by foreign or provincial universities.

At the recent meeting of the Pathological Society Dr. Rolleston showed a patella from a joint which had been for some years partially dislocated outwards. To the articular surface of the bone was apparently attached the internal semilunar cartilage. The internal semilunar cartilage being absent from its proper position. The cartilage attached to the patella was adherent to its periphery just in the way that the semilunar cartilages are to the tibia, there was the same space between the articular surface of the patella and what appeared to be the tibial surface of the internal semilunar cartilage as there is normally between the semilunar cartilages and the tibia. In the present case the cartilage was adherent for its whole depth to the patella at the upper part. The two extremities of what was apparently the internal semilunar cartilage were firmly united by a plate of cartilage the size of a shilling. This portion was underhung by a synovial pouch, as was the greater part of the body. This additional piece of cartilage lay to the inner side of the patella, consequently the supposed internal semilunar cartilage must have turned round before becoming adherent to the patella. The surface of the external condyle was eburnated and devoid of cartilage; the external semilunar cartilage was partially eroded. The internal condyle of the femur was covered with cartilage.

A special meeting of the Ophthalmological Society has brought forward a motion in the following terms: "That in view of the course of medical study extending over a period of five years, it is expedient that the Ophthalmological Society of the United Kingdom urge upon the General Medical Council the desirability for making the study of ophthalmic medicine and surgery a compulsory part of the ordinary curriculum."

Mr. Ernest Stanbury Hankin, the young Eng-

lish man of science who is said to have discovered at Berlin a "cure" for anthrax, had a very brilliant career as a student at St. Bartholomew's Hospital, where his singular aptitude for microscopical work and his general power for work made him one of the favorite pupils of Dr. Klein, the celebrated bacteriologist.

DOMESTIC CORRESPONDENCE.

Dr. John P. Gray's Experience with Tuberculin.

To the Editors.—I have read with much interest the communication of Dr. von Ruck in a recent issue of THE JOURNAL, and desire to add my experience to his, as to the favorable results to be obtained from the proper use of "tuberculin." Returning from Berlin in the early part of January, I at once began the use of the lymph in the hospital here, and have had under treatment up to date twenty cases—of which three were lupus and the remainder pulmonary tuberculosis in the first and second stages. It is not my purpose in this article to go into a full report of these cases, reserving that for a later date, but to simply give the general results. In those patients suffering from lupus a steady improvement has been noticeable, the diseased tissue has gradually sloughed off, leaving a healthy cicatrix behind, so that in all three there seems to be a reasonable hope of permanent recovery.

Of the seventeen cases of phthisis two have recovered, or at least are well to the extent that they are up to their normal weight, have no cough, or expectoration, and the physical signs in the lungs are daily improving. Eight have improved markedly in that they have gained appetites, have gained in flesh, and general strength, and the cough and expectoration have been greatly diminished. Three have improved slightly, in that the disease appears to have been checked. The remaining four have only been under treatment a short time, but two of these I hope will recover, or they are favorable cases and are improving rapidly.

As to the doctor's statement that "nowhere in this country or in Europe" a similar method of administering the lymph has been adopted, I can only say that from the first I have followed exactly the same course, beginning with a quarter or half a milligram, and gradually increasing the dose—never bringing on any violent general reactions, and never raising the amount while there was any effect to be observed from the injections. I also see from the *Hochenschrift* that the method has been adopted in some of the German hospitals.

Of course we have not had the climatic advantages that Asheville affords, and it has struck

me forcibly while observing the effects of the lymph treatment that if such good results could be obtained in the two worst months of the year, when the patients are more or less confined to the house, how much more might we hope for under favorable surroundings. Dr. Jacobi, in a recent article, hints that the future treatment for consumption will be a proper combination of climate and lymph, and feeling stronger that this is the case, I propose if possible to arrange for the treatment of a number of cases in the Adirondac region, where I am sure the percentage of cures can be greatly increased.

JOHN P. GRAY, M.D.

Utica, N. Y., March 29, 1891.

An American Medical Temperance Society.

To the Editor:—Several months since the undersigned received a communication from the Secretary of the British Medical Temperance Association, suggesting the formation of a similar organization in this country and the establishment of fraternal relations between them. The British Medical Temperance Association was organized in 1876, in London, with thirty members and Dr. Edmunds as President. It now embraces about five hundred members, with Dr. B. W. Richardson as President, and Dr. J. J. Ridge, Secretary. Among its members are many of the more eminent members of the profession in that country, and it has exerted a wide and most beneficial influence. The objects of the Association are declared to be "to advance the practice of total abstinence in and through the medical profession, to promote investigation as to the action of alcohol in health and disease, and to constitute a bond of union among medical abstainers scattered all over the country." . . . "It admits as members, registrable medical practitioners who are practical abstainers from all alcoholic liquors as beverages. It admits as associates, medical students who also practice total abstinence. Neither members nor associates are required to sign any pledge, but if such, for any reason, cease to be total abstainers, it is expected that notice of withdrawal from the Association will forthwith be sent to the Secretary." The liberty of members in prescribing alcohol as a medicine is entirely uncontrolled. The formation and active maintenance of such an Association in this country would accomplish an amount of good not easily estimated; and if those members of the profession who would favor such a step, will send me their address on postal card, I will provide a time and place for a meeting in Washington during the week of the next annual meeting of the American Medical Association in that city.

N. S. DAVIS, M.D.

65 Randolph St., Chicago.

Medical Legislation in the State of Missouri.

To the Editor:—In THE JOURNAL of March 7 appears an item relative to medical legislation in the State of Missouri, to the effect that a bill was pending to compel all medical colleges in the State to adopt three courses of lectures as a condition for graduation. The bill was unanimously recommended for passage by the committees of both House and Senate. The House passed it by the gratifying vote of 85 ayes to 22 noes. The Senate voted against the bill. As the session closes in two days there is no time to work for reconsideration, hence this most necessary reform is defeated, to the shame of Missouri. What makes the fact all the more mortifying is the contemptible nature of the opposition, all of the colleges in the State (14 in number) but one—located in St. Louis—appearing in favor of the bill. The medical profession of the State, so far as evidence shows, being overwhelmingly favorable. Powerful outside pressure was brought to bear to influence the Senate unfavorably.

The history of the bill is most interesting and extremely instructive, now that the profession all over our Nation is so busy in medical reform. The Missouri State Board of Health last year promised, through its Secretary, to follow the grand example of the Illinois Board, and in the due exercise of its proper authority defines a college "in good standing" to be such a 'one only, as among other conditions, required three years attendance upon lectures and clinics. For reasons that would take too long to explain here, the Board this year declined to take this step, but formally referred the whole matter to the Legislature, then in session. The Medico-Chirurgical Society of St. Louis applauded the bill, on resolution, and appointed a committee of three to assist in securing its passage. This committee waited on both House and Senate committee. Only in the Senate committee was any opposition made, the Dean of the objecting St. Louis college appearing. The ostensible basis of the opposition consisted in these two arguments, which will probably have to be confronted in every State where substantial medical reform in education is attempted: *First*, to require three years' attendance would work a hardship on the "poor boy;" *secondly*, to discriminate among the colleges would be "class legislation," and therefore "unconstitutional." The "poor boy" argument was vigorously worked and ingeniously applied. Among well-informed people these arguments may excite a smile, but that they should seriously be advanced and be ostensibly accepted by the Senate of a great State as sufficient ground to defeat so important a measure—what shall be said! Certainly, here is no smiling matter; particularly as this defeat will affect great interests outside Missouri. The Medico Chirurgical Society regarded

the adoption of the reform as likely to strengthen the noble work of Illinois in that direction. Also, many of the Southern States and South-western might be led by this example to enact similar desirable laws; and thus the grand advance in medical education so imperatively demanded and so long agitated all over the Union, would be accomplished.

It is a fact that there is an element in Missouri sympathizing with the malcontents in Illinois, that openly declares that the Illinois State Board of Health will be broken down in its reform measures. Our neighbors need to be on guard so long as its Legislature sits, lest some hostile bill be slipped through in disguise, or in the ruck of measures blindly rushed along in the last days of the session.

I should state that great efforts were made to carry our bill. Members of the Legislature were written to by doctors from all over the State. One Senator assured me that his pockets were full of such letters, but that he did not always vote as his constituents desired; that, in fact, he thought people ought to be at liberty to employ just such service as they wanted, that he had obtained a license to practice law simply because an oppressive statute compelled him to do so, not that he thought such restrictions necessary. Another solon with considerable violence declared that for his part he would rather employ a doctor who had never been inside a medical college; I judged this contemner of mundane illumination believed with the immortal Dogberry, that reading and writing came by nature. Still another of the *Patres Conscripti* thought the bill favored caste in society, and having been born under the British monarchy, like a sound convert to republicanism, the very sniff of such servitude was abomination of abominations.

But enough of such experiences, so mortifying to a native Missourian; it is a comfort to know that the prime mischief worker is not even a Westerner by birth. I will close by saying that the friends of the bill summed up their argument in this: A jury of intelligent physicians from any part of the civilized world will not hesitate to declare that it is *impossible* to give the most capable student an education fitting him to practice medicine, under three years' attendance upon lectures and clinics.

In the Senate committee it was protested that it was with a sense of shame that we set the limit at three years. In Europe, even in Mexico, which country requires six years, no period less than four years is recognized. No wonder American diplomas—that is an injustice to South America and Canada—no wonder diplomas from the United States are regarded as contemptible in Europe.

I sincerely trust that THE JOURNAL will make these facts known all over the Union. The Leg-

islature has not fairly dealt with its people, so that Missouri need not bear the burden of shame; the near future will put that where it shall stick.

CHAS. A. TODD, M.D.,

Of the Committee of the St. Louis Med. Chir. Society.

That "Remarkable Case."

To the Editor:—I cannot help thinking that there must be an element of deception in the very remarkable case reported by Dr. Gallraith in your last issue. Apart from the inherent improbability of the extremely high temperatures noted, it seems to me a physical impossibility, so long as the circulation of the blood is maintained, that the temperature in the axilla should be 20 degrees higher than in the mouth. A temperature of 171°, or even 151° F., can only be borne by the finger for a very brief time without severe pain, and I think it may be set down as certain, that with a temperature approaching even the lower of these points, the vapor of the breath would form a cloud, in a room at the ordinary temperature, as that of a healthy person does on a cold day. I would suggest, in case of opportunity for further observations of the sort, that the temperature be taken in the rectum, under close observation. If the case were my own I should be satisfied that if the thermometer registered higher either in the mouth or axilla than in the rectum, there was fraud somewhere, whether I could detect the manner of it or not.

In *The Lancet* (January, 1882, p. 35, American ed.), Dr. Mahomed reports a case, apparently somewhat similar, that came under his observation at Guy's Hospital. The patient, a woman, aged 22, suffering from phthisis, was repeatedly found to give readings of the thermometer ranging from 112 to 120°, and, in one instance, as high as 128° F. Although, with careful observation, he was never able to detect the way in which they were produced, he was satisfied that they were fraudulent, for the following reasons. When observations were made on several different parts at once, there were great differences in the temperatures recorded by the different thermometers. Surface thermometers gave only ordinary temperatures; neither the skin of the axilla nor the bulb of the thermometer on removal felt extraordinarily hot at times when high readings were obtained. No unusual temperatures were ever obtained by non-registering thermometers, although they were often used.

In the same volume of the *The Lancet*, p. 78, is an account by Dr. Stephen Mackenzie of the case of a woman who was under his care for an inflamed condition of the stump of an amputated thigh, who gave abnormally high temperatures on repeated occasions, the highest being 133.6°. This never occurred while she was closely watched, and she afterwards admitted that she

had produced the high temperatures by means of poultices, hot bottles, etc. Such means can, of course, be excluded in Dr. Galbraith's case, of which, I hope that he will let us know the final outcome.

W. L. WORCESTER, M.D.

State Lunatic Asylum, Little Rock, Ark., Mar. 23, 1891.

Has Omaha Found Munchausen's Mantle?

To the Editor:—The extraordinary case reported by Dr. Galbraith, of Omaha, in which the temperature of a lady with a slow pulse rose at times to 151° F., requiring the construction of new thermometers to register the phenomenon, scores another point for science. The average layman would doubtless flout such a story as ridiculous. He'd vow the doctor had conjured up this "whopper" only to see how great fools we mortals be, who should believe it. But in scientific matters of a medical nature, laymen don't know. In the presence of a wonder like this, they'd do like the old Dutch emigrant who chanced to go to a hot spring for water as he was about to camp for the night. When the hot water splashed up on his hands, he dropped the bucket in great fright and cried out to his son: "Trive on, Hans. Hell ish not far from dish place!" But it is the province of science to account for the wonderful.

No doubt this case, if properly handled—and the doctor seems to be the man to do it—will yet reach the boiling point. We have heard of people's blood boiling, and if veiding 1,000 dead bones would not make one's blood boil, why pray what could? Of course it requires the mental breadth of high professional achievement to take such marvels in.

The case is the reverse of Longfellow's "Excelsior." Dr. Holland said of it that it sounded like the truth but it was a lie. This, on the other hand, sounds like a lie, but it's the truth; not a bit of doubt about it. Perhaps some doubting medical Thomases will even ridicule this humble attempt at the Doctor's defense. No matter. Let the heathen rage and the women hiss. Science will be vindicated in the end. A medical book agent once approached a neighbor of mine to sell him the latest thing out in surgery. "No," said the Doctor, "I've no time to read it. I already have 10,000 volumes in my medical library, and besides I have to ride twelve miles every day to catheterize a lady from whose bladder I draw ten gallons of water every twenty-four hours." The agent was a layman. He couldn't understand it. He was dumbfounded at the Doctor's solemn asseveration of a scientific fact, and pronounced him "the monumental liar of America." The Doctor not having a string of titles to his name, the agent thought he had no license to lie like that. But the ignorant fellow simply didn't know. That's one great advantage the trained

physician has. He can take in the most astonishing revelations of science without wincing.

JAMES L. TAYLOR, M.D.

Wheelersburg, Ohio.

ASSOCIATION NEWS.

American Medical Association.

THE COPYRIGHTING OF THE PROGRAMME. The attention of the Committees having charge of the compiling and printing of the Official Programme is called to the following resolutions unanimously adopted at the Nashville meeting:

WHEREAS, Certain parties without authority are presuming to make use of this Association for the furtherance of advertising interests, therefore

Resolved, That at all future meetings of the Association such publications be excluded from the place of meeting either of the General Sessions or of its Sections.

Resolved, That in the future each Chairman of the Committee of Arrangements be directed to procure a copyright of the Official Programme, to the end that the financial rights of the Association may be protected by due process of law.

RAILROAD ARRANGEMENTS.—Full particulars of the Railroad Arrangements for the Annual Meeting at Washington will be published in our next issue.

NOTICE TO SECRETARIES OF SECTIONS.—The programme should be in hand one week before the meeting of the Association. It will be impossible to print correctly a list of addresses and papers received after that date. Secretaries of Sections will insure accuracy in the programme, and greatly facilitate the work of the Committee by sending their lists in time.

C. H. A. KLEINSCHMIDT, M.D.

Secretary Com. Arrangements.

We desire to emphasize the request of Secretary Kleinschmidt for the early completion of the programmes of the various Sections, and hope to present the Preliminary Programme in THE JOURNAL before the meeting. The Official Programme will be issued promptly by the Committee of Arrangements. We are grateful to know that such efficient action has been taken by the officers of the Sections, and the prospect now is that the next annual meeting will exceed in interest any that have preceded it.—Ed.

BOOK REVIEWS.

AUSCULTATION AND PERCUSSION. By FREDERICK C. SHATTUCK, M.D., etc. Detroit, Mich.: Geo. S. Davis. 1890. Pp. 121.

This is the concluding number of Series IV of the Physician's Leisure Library.

The work opens with seven diagrammatic plates which, were it not for the confusing numbers and letters with long "fingers" to denote their intention, would enhance the value of the text in no slight degree. A physician's life is generally made up of too few hours, and he can therefore ill-afford the struggle of deciphering no less than seventeen tracings or references on a single plate of small size. It will be seen that the placing of such requirement in a "Leisure" library is smilingly significant.

The text is orthodox, dealing first with the lungs, where 56 pages are devoted to a clear and concise statement of the physical signs in health and disease. Then follows Part II—heart and aorta—the concluding chapter of which, however, touches upon physical exploration of the liver, spleen, stomach, and pancreas. Altogether this little manual will find a place of some value.

A GUIDE TO THE PRACTICAL EXAMINATION OF URINE. For the use of physicians and students. By JAMES TYSON, M.D., etc. Seventh edition. Revised and corrected. With a colored plate and wood engravings. Philadelphia, P. Blakiston, Son & Co. 1891. Pp. 255.

No important change has been made in issuing a new edition of this handy little volume. The general arrangement and plan of the work makes it a ready guide for the student, as well as enabling a quick reference for the busy practitioner.

Prof. Tyson still holds—and we do not know but wisely—to the superior reliability of the time-honored "heat" test for albumen. In the light of claims—which are not without well-accepted authority—put forth from time to time of late years, we were prepared to see their advocacy or adoption; but in language not to be misunderstood the author treats the claims honestly, and as honestly expresses his thorough satisfaction with those tests which in his hands have left but little more to be desired.

SPECIAL CORRESPONDENCE.

Shall The Journal be Removed to Washington?

WHAT OUR ADVERTISING PATRONS HAVE TO SAY ON THE REMOVAL QUESTION.

To the Editor:—Permit me to request the insertion in THE JOURNAL of the accompanying circular and blank sent out to our advertising patrons, with their replies thereto in tabulated form. My reason for seeking space in your columns is the desire that the members of the Association may be fully informed as to how business men, who contribute nearly one-half the income of THE JOURNAL, look upon the proposition to remove it to Washington. Though the majority of our advertisers are not members of the Association, still their opinion, coming as it does from practical business men having a financial interest in its success, should have weight in the settlement of this question.

Some members may look with disfavor upon this method of gauging the business future of THE JOURNAL, to such I would say, most respectfully, that when the advertising interests of THE JOURNAL were confided to my care I found them very low, but by persistent and systematic work have increased the receipts from that source three hundred per cent. This statement is made to bring out the point that the bulk of this increase is due to having proved to the satisfaction of advertisers that THE JOURNAL is THE profitable medical advertising medium of the West.

It was therefore desirable to obtain their views in the premises, and after obtaining them to submit them to the members of the Association as detailed in the table on pages 536-7, which shows that 15 voted for Washington, representing 13 per cent. of the cash receipts from advertising for the financial year just closed; 45 for Chicago, and a few not voting. J. HARRISON WHITE, Office of THE JOURNAL, Business Manager, 65 Wabash ave., Chicago.

Dear Sir:—Some members of the Association are desirous of making Washington the permanent home of THE JOURNAL, and the question is to come before the members at their annual meeting next May. Being of the opinion that the advertising patrons who contribute so largely towards its financial success should have an opportunity of expressing their views on the matter I ask you to consider the question in all its bearings, and give me your reply at an early date. Very truly yours J. HARRISON WHITE, Business Manager.

Chicago, January 2, 1891

PLEASE FILL OUT BLANKS AND RETURN IN ENCLOSED ENVELOPE

Do you favor the removal of the Journal of the American Medical Association from Chicago to Washington?
Would you consider the Journal of the same value to you as an advertising medium if located in Washington?
Remarks
Signed

To the Editor:—The question of the removal of THE JOURNAL from Chicago to Washington, which is now being discussed by many physicians in every part of the United States, is, to my mind, clearly opposed by a large majority of the members of the Association—and I, for one, say, Let it remain where it is, a place which is approved of by the great majority, as I firmly believe.

B. S. WOODWORTH, A.M., M.D.

Fort Wayne, Ind., March 28, 1891.

To the Editor:—Except as I desire to see THE JOURNAL represent the best thought and the highest standard of the American medical profession, I am in no way interested in its place of publication nor in who edits it.

I do not know the origin of the agitation to take THE JOURNAL to Washington, but I surmise that it arose out of a feeling that some change was desirable.

I do not know how much editing the present editors feel justified in performing, nor exactly what is meant by the term "supervising editor" employed by Dr. Reed in his communication in THE JOURNAL of March 28, but certainly the "supervision" has been somewhat lax. Doctors are not always good writers, I have no reference to the old illegible prescription story, I mean that they do not always pay much attention to the rules of grammar or composition. And even those who have a message of importance to communicate, are not by any means direct and certain in their statements.

My impression of editorial duty extends beyond writing leaders, and making up the contents of a number of THE JOURNAL, and until the editors feel warranted in rigidly enforcing the ordinary and reasonable rules of composition, and either editing or rejecting all communications which make both writer and JOURNAL ridiculous, there will continue to be dissatisfaction, whether THE JOURNAL is published in Chicago or Washington.

Dr. Reed's comparisons are very lame. Apply his remark about employing a practical physician or surgeon. Does any one for a moment suppose that if Dr. Reed

WHAT THE ADVERTISERS SAY ABOUT IT.

NAMES AND ADDRESSES OF ADVERTISERS.	For Removal Against Removal	REMARKS.
Antikamnia Chemical Co., St. Louis, Mo.	1	In our opinion a journal located in an active business centre is more in touch with business necessities, and quicker to respond to new ideas, than others even though they may be in an aesthetically located under the eaves of the Capitol.
Armour & Co., Chicago.	1	We are not deeply interested in the question.
Baker, Charles S. & Co., Chicago.	1	
Baltimore College Physicians and Surg., Baltimore, Md.	1	We wish the Journal continued and increased success.
Battle & Co., St. Louis, Mo.	1	Washington is a political centre and not a business centre
Bernd, Henry & Co., St. Louis, Mo.	1	To any other Western city. "Ira." We do not favor anything that will take prestige away from the West. We do not see why Washington is any better than any other city. From a commercial standpoint it is the poorest city in the U. S.
Blakely, C. H. & Co., Chicago.	1	No. Would not be of same value to us.
Brown, Drs. Geo. & Geo. A., Barre, Mass.	1	
Caldwell, Frank H., Sanford, Fla.	1	We consider Chicago the most desirable place in the U. S.
Canton Surgical and Dental Chair Co., Canton, O.	1	
Chaim, Adolph, Chicago.	1	Yes.
Channing, Dr. Walter, Brookline, Mass.	1	Dr. John E. Owens, Chairman of Adv. Com., objects to the removal.
Chicago Medical College, Chicago.	1	Dr. D. A. K. Steele, secretary, writes: In reply to your note of inquiry regarding the desire of some members of the Association to make Washington the permanent home of the Journal, I would state that it is my opinion, as one of the advertising patrons of the Journal, that its removal to Washington from Chicago would be a mistake. I am decidedly in favor of its continuation here.
College of Phys. and surgeons, Chicago.	1	
Cooke, George F., M.D., Oxford, O.	1	No. Would not be of same value to me as an advertising medium.
Crittenden, C. N., New York City.	1	We deem it quite inadvisable for your publication to remove to Washington, D. C., as it would, in our judgment, lose its prestige, owing to the competition it would be obliged to meet from other medical journals.
Cincinnati Sanitarium, College Hill, O.	1	Dr. Orpheus Exerts, Supt., writes: I see no sufficient reason for removing the Journal from Chicago, and if it is to be moved should not favor Washington as its permanent home.
Codman & Shurtleff, Boston, Mass.	1	Decidedly No. We think it much better that the Journal should remain where it is, as we value it for its present large circulation, which would be necessarily lessened if the proposed removal were effected.
Dauchy & Co. (Liebig Ext. of Beef), New York City.	1	Our opinion is decidedly adverse to the removal of your paper from a great business centre like Chicago to the city of Washington. We do not see how it is possible for the paper, if published from the latter point, to exert as immediate an influence on business men as if it issued from Chicago.
Detroit Coll. of Medicine, Detroit, Mich.	1	No. Would not be of same value as an advertising medium.
Drevet Manufg Co., New York City.	1	Your Journal has been giving up a large number of returns, and we feel confident that its removal to Washington may increase the number of your subscribers.
Fredigke, Dr. Charles, Chicago.	1	No value to us if removed.
Garden City Bindery, Chicago.	1	Yes.
Gardner, R. W., New York City.	1	The present headquarters of the Journal on geographical, scientific and editorial grounds cannot be improved upon, in my judgment.
Gray, J. Lucius, M.D., Chicago.	1	
Gorges, Mrs. J. A., Rogers Park, Ill.	1	Yes.
Hance Bros. & White, Philadelphia.	1	From the point of view of my customers, the Journal would not derive any advantage from being located in Washington that it does not possess in Chicago, while Chicago in a business way offers greater facilities than Washington.
Haldensten, J. (Apollinaris Co.), New York City.	1	No! In letters almost an inch in depth.
Hortick's Food Co., Racine, Wis.	1	We can see no objection to Chicago, but if a change seems necessary, why Washington is neutral ground, and should satisfy everybody. However, the present tendency seems to be for all roads to lead to Chicago.
Imperial Granum Co., New Haven, Conn.	1	I am quite confident that the business interests of the Journal would suffer loss by the proposed change.
Keener, W. T., Chicago.	1	Yes.
Kirkley, C. A., M.D., Toledo, O.	1	
Lagorio, Dr. A., Chicago.	1	
Lambert Pharmacal Co., St. Louis, Mo.	1	New York, Philadelphia, St. Louis, Boston, Baltimore and Cincinnati support weekly medical journals. Evidently the Association Journal must answer the purpose of a weekly for our second largest city. In giving up this perquisite you offer an excellent opportunity for the establishment of a weekly medical journal as a business enterprise, and force the Association Journal into more direct competition with the great medical weeklies of the East. In our opinion it will suffer severely by the change.
Levytype Co., Chicago.	1	
Madson, William, Chicago.	1	
Magruder, G. L., Dean Georgetown University, Washington, D. C.	1	
Marcy, Henry O., M.D., Boston, Mass.	1	No. (See his letter as a member in the Journal of January 31.)
Mattison, J. B., M.D., New York City.	1	Yes. Most heartily favor the change. It is a National journal, and should be published at the National centre.
Murray & Mitchell, Memphis, Tenn.	1	No. Would not consider it of the same value to us as an advertising medium if removed to Washington
Med. Dep't Columbian University, Washington, D. C.	1	To the first question, yes. To the second, not necessarily the same, but as good, or perhaps better. The Journal should be central, National, and weaned from all local interests.
Med. Dep't University of Michigan, Ann Arbor, Mich.	1	Dr. W. A. Campbell, Sec'y, writes: From the standpoint of an advertiser, and for our use, I consider Chicago the best location for the Journal.
Millard, P. H., M.D., Minneapolis, Minn.	1	Dr. H. Millard, Dean Med. Dep't Univ. of Minnesota, writes: The removal of the Journal will forfeit our entire patronage.
Movins, J. & Son, New York City.	1	No.
McIntosh Battery and Opt. Co., Chicago.	1	No. Dr. McIntosh verbally stated that they would stop their advertisement if the Journal is removed from Chicago.
New Table Co., St. Louis, Mich.	1	No. Chicago is the second great business centre of the U. S., and in twenty years will be the first in importance. Washington will not be anything but the political quasi centre.
Parrish, Wm. G., M.D., Burlington, N. J.	1	It appears to me that the Journal would have the same circulation through the West, where it is well known, if at Washington as a headquarters, and would gain still more East and South by the change, in subscribers and advertisers.

NAMES AND ADDRESSES OF ADVERTISERS.

WHAT THE ADVERTISERS SAY ABOUT IT.

For
Removal
or
Removal

Farke, Davis & Co., Detroit, Mich.	1	We are satisfied as it is. The management of the Journal of the A. M. A. is located in Chicago is convenient to us at Detroit, and it being assumed that the Journal has a large local circulation in the West incidental to its publication in that section of the country, we believe that it exercises a more satisfactory influence for Western advertisers than would be the case if located in the East.
Peacock Chemical Co., St. Louis, Mo.	1	We believe the Journal would wield the same influence from either point of view, the present location and management hard to improve upon.
Phillips (C. H.) Chemical Co., New York City.	1	Do not favor removal. Would not be so valuable to us as an advertising medium.
Post-Graduate Med. School, Chicago	1	Dr. W. Franklin Coleman, the secretary, writes: The East is well supplied already with our weekly Journals. The P.-G. Med. School desires to come in contact through advertising with Western physicians. The removal of the Journal to Washington would all lessen our interest, and I think that of the Western physicians, in it.
Rio Chemical Co., St. Louis, Mo.	1	We do not think the removal of the Journal to Washington would make any material difference.
Robinson-Pettit Co., Louisville, Ky.	1	We would say that in our opinion Chicago is a better point for issuing the Journal than Washington would be, on account of its central location.
Ruehsam, John E., Washington, D. C.	1	I favor the removal. The Association will grow with the Nation's Capital.
Rush Medical College, Chicago.	1	Dr. J. H. Etheridge, Sec'y, writes: An indifferent. It would be very interesting to enquire what criticism of the local directory of the Journal has led up to this move. Perhaps there is something written between the lines that would be interesting.
Sander & Son, Dillon, Iowa	1	We favor such a move as the right step at the time in the right direction.
Schieffelin, W. H. & Co., New York City.	1	We believe the Journal to be a good medium for advertising and can express no preference as to the location of its office of publication.
Scott & Bowne, New York City.	1	We desire to say that the location of your Journal in Chicago is very much more to our interest and advantage than it would be located in Washington. As we are well represented in Eastern Journals, we do not think we would care to advertise in it if you changed to that city.
Sharp & Dohme, Baltimore, Md.	1	We are in favor of transferring the permanent home of the Journal to Washington.
Sharp & Smith, Chicago.	1	No. We would not advertise in the Journal if same was located in the East.
Smith, Bradner & Co., Chicago.	1	Dr. H. H. Mudd, Dean, opposes removal and considers the Journal would not be of the same value as an advertising medium.
St. Louis Med. College, St. Louis, Mo.	1	Since the Journal is a National affair, it should be located centrally. Next to St. Louis, we prefer Chicago. If we have a voice in the matter we must proclaim for the West.
Sultan Drug Co., St. Louis, Mo.	1	Yes.
Tarrant & Co., New York City.	1	(See Dr. Crothers' letters in the Journal of January 31 and March 21.)
Tyndale Euclaytus Co., Chicago.	1	The circulation and the quality of a medical journal are the questions of most importance to the advertiser. Your Association being a National one, it is quite proper, we should venture to say, that its Journal should be published in Washington.
Walnut Lodge Hospital, Hartford, Conn.	1	Every advertiser will admit that there are too many medical journals. About three-fourths of them are located East of Indiana and North of Washington. Do not aggravate matters. Stay where you are. There you are the leading weekly medical journal. Here you will have to take fourth or fifth place.
Warner, Wm. R. & Co., Philadelphia	1	
Woodruff, I. D. & Co., New York City.	1	

wanted a journal of real literary and scientific merit published he would employ as editor any one merely because he was a practical physician, if he were not satisfied that his practical physician knew when a sentence had a predicate and had the courage to put one in when it was necessary in Dr. Blank's very good "practical" article on pneumonia, or to take out the double negative from Dr. J. Doe's otherwise readable article on fractured patella?

I am not questioning for a moment the ability of the present editorial staff, but I have often, in reading THE JOURNAL, queried whether the "intelligent compositor" or "vigilant proof-reader," or the—shall I say timid—editor was responsible for some of the assaults upon our mother tongue which so often appear in the pages of THE JOURNAL.

As the voters who have voted through THE JOURNAL appear to be nearly all of one mind, let us hear from them and others as to how much editorial cutting and mending they are willing their manuscripts, correspondence as well as contributions to the scientific papers, shall undergo before being sent to the printer.

If the Association will sustain the editors and the editors will fearlessly edit the articles before sending them to the printer, I think there will be a steady increase in the value and reputation of THE JOURNAL.

We may not, like one of our law-makers, "care much for abroad," but I have reason to know that THE JOURNAL, through some of its articles, has not reflected much credit upon the literary ability of the profession.

E. N. BRUSH, M.D.

Philadelphia, March 30, 1891.

To the Editor:—I know of no reason why THE JOURNAL should be moved from Chicago. It always reaches

me on time and is chock full of the very best medical literature. I prefer to let well enough alone.

D. A. WALKER, M.D.

Friendship, Tenn., March 31, 1891.

To the Editor:—It is immaterial to me where THE JOURNAL is published, provided it is conducted exclusively in the interests of scientific medicine and the greatest good of the profession. That it does not fully meet the requirements of either now is a source of dissatisfaction, and creates a desire for change in the minds of many members of the Association. But, if these deficiencies can be corrected without removal, it is better to allow it to remain in Chicago, for the present at least, to try. Believing that it can be thus improved and brought up to the ideal standard where it is, and disclaiming all carping criticism, I offer suggestively the following to that desirable end.

1. In the first place, then, THE JOURNAL should be printed on plain and not on glazed paper, which from its reflection, dazzles the eye, irritates the optic nerves, muscles and lobes, brain and mind, and sympathetically other parts of the system, thus impairing the sight, causing eye-strain with spasm and twitching of muscles, ocular and cerebral hyperemia, dizziness, headache, neuralgia, melancholy, petulance, irascibility, and other disorders of the physical, mental and moral nature, more or less serious. It is thus a serious obstruction to the acquisition of knowledge and preservation of health of the whole being, body and soul, which should be discarded as dangerously insanitary and wholly unscientific, especially discredit-able in a publication under the auspices of physicians, the special exponents thereof. Besides, it is not only antagonistic to the well-being of mankind, but also to commercial success, for no sensitive or enlightened person will

even willingly read, except occasionally and for brief periods, much less subscribe for such a glaring sight and health-destroying publication, no matter how cheap or meritorious it may be. This evil can and should be speedily rectified by substituting plain for glazed paper, not only in *THE JOURNAL*, but all other publications, and people should protect themselves by taboos all printed matter on glazed paper in the interests of good sight, good health, of body and mind, good temper and morals, education, enlightenment, development and civilization.

2. While *THE JOURNAL* should stimulate original research, and uphold American medicine especially, it should not be provincial or subservient to foreign ideas, but as cosmopolitan as medicine itself, truth being universal, teaching, developing and culting it from all sources, with a due regard to the philosophy as well as the art of medicine, for the highest educational purposes, and to enlighten the concrete with the abstract knowledge of truth, so that principles and practice, science and art shall go together, as they are mutually essential to the perfect development of medicine. The prevention and treatment of every disease is a problem to be solved in accordance with mathematical, logical and scientific principles, as a guide to insure the greatest certainty and success in both. Hence empiricism can only be employed with advantage in so far as it is necessary for disclosing, testing and determining the truth. Thus enlightened empiricism or rational experiment inductively leads to the advance of the science, and deductively promotes the philosophy of medicine (which, by the way, should be the crowning part of the curriculum of every medical college), while blind empiricism is merely chance experiment and arrant quackery. Secrecy and assertion with wild, haphazard or irrational experimentation are unscientific, and involve in confusion, doubt, disappointment, disaster and death.¹ Thus accurate observation, experiment and experience, guided by reason, aided by judgment, leads directly to a knowledge of the truth in medicine as in everything else, and it is the mission of *THE JOURNAL* to present this in the most definite, condensed and available form with as little erroneous or extraneous matter as possible, so as to educate and enlighten the profession to the fullest extent.

3. The department of notes and news should be as brief, impersonal, professional and general as possible, noticing only subjects of immediate practical interest to physicians everywhere, and omitting as "flat, stale and unprofitable" all tending to promote personal, local, or extraneous interests of any kind, for it is merely gratuitously advertising them, and concerns few beyond those mentioned. The space thus occupied and wasted should be utilized with useful medical ideas of import to practitioners in general as contributing to the relief of the afflicted and suffering, and desirable to those trying to solve the problems of health and disease, life and death, everywhere throughout the world.

4. As the representative of the American Medical Association and scientific medicine *THE JOURNAL* should avoid any encouragement to empiricism or quackery, domestic or foreign, and rigidly exclude from its advertising as well as reading pages all articles relating thereto in every shape and form, especially secret and proprietary agents of polypharmaceutical and physiologically incompatible admixtures or hodge podge of drugs, under fanciful and misleading names, or some ingredient thereof without the full formula, or otherwise concealed so that physicians cannot fully know their constituents and determine accurately their doses and uses, independent of the prejudiced and often erroneous statements of their makers and vendors. *THE JOURNAL* is not the organ of any one person, institution, clique, trade, local or extraneous interest whatsoever, but of the Association or profession in general, and it should not be the medium

of advertising nostrums, or secret, disguised, and quack preparations of any kind. We rightly denounce the religious and secular press therefore, yet inconsistently allow our own professional organ to be used for the same base purpose for a little pelf, thus degrading it, ourselves, our profession, and medical science. Of course, all persons, physicians included, are justly entitled to a due recompense for their discoveries in medicine as in everything else whenever made known, but secrecy and deception therein is opposed to progress and should not be tolerated, by physicians at least, as they prevent those who are induced to use them from comprehending their nature, acquiring correct knowledge, and intelligently performing their duties to their patients, while giving false ideas and experience detrimental instead of beneficial to those most concerned. Hence the evils therefrom are manifold in being fraudulent and injurious throughout, for besides the immediate pecuniary loss, there is often direct harm or failure to promote the welfare of the sick and suffering with humanity in general, as well as detrimental to medical science. While life is based upon reciprocity, it is only in the domestic circle that it is of a more purely personal nature, for outside of that it must necessarily be more exclusively of a commercial character, though insensibly it merges throughout into free efforts for the relief of the helpless and unfortunate, yet it is only those favored with a surplus of health and wealth who can afford to work gratuitously for the good of mankind. But many are so selfish as to have no feeling for their fellows, as they will work and starve them to death, and even rob the sick and afflicted for self-aggrandizement. Such are like sponges that absorb everything they can, and give out nothing but what they cannot hold and what is squeezed out of them. These greedy sharks would monopolize everything and leave others to suffer and perish, they must, therefore, be actively antagonized to restrain their cruel propensities, especially in the case of empirics, nostrum-makers and quacks of every kind, to oppose and afford them as little opportunity as possible to rob the sick and thrive on the ignorance, suffering, and misfortunes of others, particularly by refusing to aid them in their nefarious schemes to disseminate a knowledge and promote the use of their empirical preparations under the sanction of medical journals and physicians, who thus become accessories to all the evils therefrom. Besides, the tendency of this pernicious practice and support of charlatanism is to degrade the profession itself and reduce physicians to mere medical mechanics, not to be thinkers and leaders, but dependents and servants, to follow the directions of empirics, nostrum-makers and traders. Hence *THE JOURNAL* should be kept free from all such objectionable matter and cease to be an agent of evil, for which the members of the Association are responsible, and should it not be so improved where it is, then it would be better to remove it to Washington or some other place where it could attain the ideal National, professional and representative character, exempt from all such obnoxious business, quackish, and other degrading influences.

5. Finally, *THE JOURNAL* should be under stricter medical supervision throughout all its pages of reading and advertising alike, inculcating therein most fully and purely the principles and practice of scientific medicine, both preventative and curative, refusing to pander to empirical, personal, clique, local, trade, nostrum, quack or extraneous interests of any kind, so as to insure the greatest progress and highest development of rational medicine. It would thus become a shining exponent of the science and philosophy of medicine and leader of professional knowledge, not only a creditable organ of the American Medical Association, and a source of enlightenment and pride to each member thereof, but to every physician of this country and abroad, as its beneficent influence would extend indefinitely throughout the world.

GEO. J. ZIEGLER, M.D.

Philadelphia, April 2, 1891.

¹ Here follows a criticism of the "K'ch occult lymph" which on account of its length, and being foreign to the subject under discussion, is omitted.

Editorial Opinions of the Medical Press.

A question at present agitating the American Medical Association is whether The Journal shall be removed from Chicago, its present place of publication, to Washington, D. C. The subject has just now been brought into prominence through a special meeting of the Trustees of the Association, held at Washington, D. C., November 13, 1890. This meeting was called by the President, Dr. Hooper, of Little Rock, Ark., upon a requisition signed by a majority of the Board, for the special purpose of considering the question, upon which a special committee had been appointed. The following report was then received and adopted:

Resolved, That the sense of the Committee be that the home of The Journal of the Association should be permanently at Washington, D. C.

Resolved, That the Trustees incorporate the foregoing resolution in their report to be presented at the next meeting of the Association.

The following resolution was also adopted.

Resolved, That the Trustees recommend the members of the Association, of the various State and local medical societies in affiliation with the Association, to contribute or subscribe funds for the erection of a permanent building as a place of meeting, as well as a library and office for the American Medical Association.

The immediate result of this action, and its subsequent publication in The Journal, has been a very animated discussion, into which considerable heat and not a little personal feeling seems to have been injected. This is exceedingly unfortunate. The question is not in the least a sectional one, and should have no possible personality involved, but must be considered on the broader basis of the welfare of The Journal, and, therefore, of the Association, and it is from this standpoint that we shall discuss it. We shall assume, as we believe, that the committee making the recommendation did so under the conviction that it was "for the best interests of all concerned," and in seeking a reason for this action find the second resolution, that really seems to be the key to the situation. The proposition to establish a home for the Association is not new; it emanates from the same sentiment that would hold every second meeting at the National Capital. The establishment of a permanent home in Washington, with annual meetings in that city, logically carries with it the removal of The Journal to headquarters. We do not believe for a moment that this scheme will ever be carried out, or that the Association will deliberately adopt a suicidal policy. The American Medical Association must be of the whole United States; it must be thoroughly National; with its loose and defective organization, a tendency to centralization would be fatal to its existence. The Association should meet each year in a different city, and, as far as practicable, in localities widely apart. At every meeting there is a fresh accession to the membership, drawn largely from the surrounding country, and a fair proportion of these accessions become permanent members. Does any one suppose that similar additions would take place if the annual meetings were held year after year in Washington, or any other city? It needs the immediate influence, the presence of a large meeting and the enthusiasm evoked to compel this annual increment. To a large number of the profession, the American Medical Association is only a name, and this may be emphasized by the comparatively small number who have embraced the privilege of joining "by application." To one who has attended a meeting, the Association is a living reality, and incidents happening twenty or twenty-five years ago have, as we know, been cherished and oft repeated by those who in that period may have met the Association at most but twice. The centre of population is rapidly moving westward, and with this increase of population the number of physicians located in the West has proportionately increased. The increase has been greatest in the Pacific Coast States and Territories; yet how many physicians of this vast region could afford to attend a meeting held in Washington, and to take an expensive trip, involving an absence of at least three weeks,

It may be urged that a permanent home and the removal of The Journal to Washington does not imply that meetings shall be held in that city, but we regard it as an entering wedge that should certainly be withdrawn.

As for the question of the removal of The Journal, the reasons so far advanced seem to be mainly sentimental. We have watched the medical press carefully for some solid argument in favor of this change, but none are forthcoming, while the testimony against it is overwhelming. The present location is central; Chicago, as a great city and trade centre, offers facilities for publication that are not surpassed by other cities; as a great railroad centre its opportunities for distribution and mail service are unequalled. This latter fact chiefly concerns us in the West, as The Journal now reaches us on Monday two days in advance of any of the Eastern weeklies, and three days ahead of all but one. It has been stated that 85 per cent. of its advertisers have expressed a preference for Chicago as the place of publication. While we do not accept these figures at their face value, we still believe that a Journal published in Chicago is much more likely to have a large amount of advertising than the same journal in Washington. Outside of these facts there are no propositions for discussion. The Journal is not what its best friends desire it to be. On the other hand, it is questionable whether under existing circumstances it could have been made better, and certainly its present location has had nothing to do with the matter. There are two factors needed to make The Journal what we desire it to be—(1) The American medical journals; (2) A large and increasing income. 1. An able and competent editor, who shall be allowed to edit The Journal untrammelled by the direction or supervision of any authority save that of the Association in general. These factors can be attained as well in Chicago as in any other city, and a careful study of the question shows that there are unmentioned conditions giving her superior advantages. The question is to be voted upon at the next meeting—(a) the question of removal to Washington is to be voted upon at Washington—a manifestly unfair proceeding, giving, as it does, a preponderance to the local vote. Arrangements should be made for an early canvass of the entire Association, thus giving every member the opportunity of expressing an opinion, though not of voting.—*Confidential Medical Times*, March, 1891.

For years there has been a move on foot by certain self-constituted custodians, who flatter themselves that they possess all the brains and refinement of the American Medical Association, to remove The Journal of the Association to Washington. These "wise men of the east" whose habitation is circumscribed by the Alleghenies on the West, the Potomac on the South, the St. Lawrence on the North and the pine clad hills of Maine on the East, would take to themselves the sole prerogative of dictating the editorial utterances of The Journal. This clique has its head at Washington, D. C. Not satisfied with the honor the capital can confer upon them, this admiration society, composed of medical politicians, would take to themselves the complete control of our National Journal and crack its fingers in the face of the great South and West. Is this right? Is it just? Will it be tolerated?

The reason given, ostensibly, for removing The Journal to Washington, is that it, being a national organ, should be published at the capital of the nation. This is the merest nonsense. The truth is, a few of those would-be censors desire to get control of The Journal for no other reason than self glorification. Let every member of the Association from the South and West, who attend the next session, see to it that this move to rob them of their just dues be unceremoniously decapitated.

The great West has about ceased to bow its knee to the sweet-scented, velvet-fingered, ethereal East. Washington City is scarcely large enough to make a respectable

suburb to Chicago, yet they—the medical politicians and presto pass quick manipulators—have the immaculate gall to attempt to gobble up and control our National Journal. Can they do it?

In our next issue we shall give some facts and figures demonstrating the absurdity and injustice of the selfish move.—*The Texas Health Journal*, March, 1891.

MISCELLANY.

CONVENTION OF MEDICAL LICENSING BOARDS.—At the suggestion of Dr. William Perry Watson, Secretary of the State Board of Medical Examiners of New Jersey, Dr. Rauch has called a meeting of one or more representatives of the various medical licensing boards in the United States, to be held in Washington, D. C., on May 6, during the meeting of the American Medical Association, in order to effect a permanent organization and to make rules and examinations as nearly uniform as possible. Licensing boards now control medical practice in 21 States. It is expected that much good will come of this meeting.

THE BIG FOUR AND THE ANNUAL MEETING OF THE ASSOCIATION.—To members of the American Medical Association who contemplate attending the annual Meeting at Washington, D. C., May 5th to 8th, a few words in regard to the best means of reaching Washington will no doubt prove acceptable. The recognized line from Chicago is the Popular Big Four Route in connection with the Scenic Chesapeake & Ohio Ry., from Cincinnati running via White Sulphur Springs, through the beautiful mountain regions of the Virginias, over its own tracks into the City of Washington.

Passengers via this popular line have the choice of two elegant trains, starting from Lake Street Depot, Chicago,—the morning train equipped with elegant parlor cars, cafe dining car and luxurious coaches, makes connection at Cincinnati with the Famous "Fast Flying Virginian" via the C. & O. Route, assuring passengers of first class service, including Dining Cars, for the entire trip. The evening train from Chicago is equipped with private compartment buffet sleeping car, standard Wagner palace sleeping car and elegant reclining chair car and makes connection with the "Washington Fast Line" via the Chesapeake & Ohio Ry., affording a day-light ride through the beautiful Ohio Valley, and across the scenic Blue Ridge Mountains into the Capital.

These trains are vestibuled throughout, provided with an unequalled dining car service and afford every comfort and convenience of modern railroading. For tickets and full information call on or address J. C. Tucker, General Northern Agent 121 Randolph St., Chicago, Ill., D. B. Martin General Pass. Agent Big Four Route Cincinnati, O.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from March 28, 1891, to April 1, 1891.

By direction of the President, the following named officers are detailed for duty under the Intercontinental Railway Commission appointed under a provision in the Act of Congress approved July 4, 1890, for the purpose of making "a preliminary survey for information in respect of a continental railway recommended by the International American Conference, and they will report in person to the Commission in this city accordingly: Capt. Edgar L. Stevens, Third Cavalry; First Lieut. Stephen M. Foster, Fourth Artillery; First Lieut. Lyman W. V. Kennon, Sixth Cavalry; First Lieut. Andrew S. Rowan, Ninth Infantry; Second Lieut. Samuel Reber, Fourth Cavalry; Second Lieut. Charles A. Kitchen, Third Cavalry; Capt. William C. Shannon, Asst. Surgeon U. S. A., for duty as medical officer of the party to which he may be attached. Par. 5, S. O. 73, A. G. O., Hdqrs. of the Army, Washington, April 1, 1891.

Major David L. Huntington, Surgeon, on being relieved by Capt. Henry G. Burton, Asst. Surgeon, from duty at San Diego Bks., Cal., will report in person to the commanding General, Dept. of Ariz., at that post, reporting by letter to the commanding General Div of the Atlantic. Par. 5, S. O. 71, A. G. O., Hdqrs. of the Army, March 30, 1891.

Capt. Henry G. Burton, Asst. Surgeon, now at San Diego, Cal., on sick leave of absence, is relieved from further duty at Vancouver Bks., Washington, and will report in person to the commanding officer, San Diego Bks., Cal., for duty at that post, relieving Major David L. Huntington, Surgeon, and reporting by letter to the commanding General, Dept. of Ariz. Par. 5, S. O. 71, A. G. O., Hdqrs. of the Army, March 30, 1891.

Capt. Van R. Hoff, Asst. Surgeon, leave of absence granted in order of, C. S. P. Riley, Kan., is extended twenty-three days. Par. 5, S. O. 72, Dept. of the Missouri, March 27, 1891.

Major Joseph B. Girard, Surgeon, is relieved from duty at Ft. Lowell, Ariz., to take effect upon the withdrawal of the troops from that post, and will report in person to the commanding officer, Alcatraz Island, Cal., for duty at that station, reporting by letter to the commanding General, Dept. of Cal. By direction of the Acting Secretary of War. Par. 5, S. O. 70, A. G. O., Hdqrs. of the Army, Washington, March 28, 1891.

Official List of Changes in the Medical Corps of the U. S. Navy, for the Two Weeks Ending April 1, 1891.

P. A. Surgeon Howard E. Ames, promoted to Surgeon March 10, 1891.

P. A. Surgeon Stephen S. White, ordered to the U. S. S. "Baltimore," Asst. Surgeon Geo. McC. Pickrel, promoted to P. A. Surgeon March 27, 1891.

Surgeon Wm. Martin, ordered to Naval Rendezvous, San Francisco, Cal.

Medical Inspector C. H. White, appointed Fleet Surgeon, Pacific Station.

Asst. Surgeon H. N. T. Harris, ordered to the U. S. receiving ship, St. Louis.

P. A. Surgeon George McC. Pickrel, ordered to Naval Hospital, New York.

P. A. Surgeon C. W. Rush, ordered for duty with Intercontinental Railway Commission.

P. A. Surgeon F. N. Ogden, ordered for duty with the Intercontinental Railway Commission.

Asst. Surgeon James H. North, Jr., ordered to the Navy Yard, New York.

Surgeon F. L. Stephenson, ordered to the U. S. S. "Marion."

P. A. Surgeon T. P. Berryhill, ordered to the U. S. S. "Marion."

Medical Inspector C. H. White, ordered to the U. S. S. "Baltimore."

Medical Inspector J. H. Clark, ordered to the U. S. S. "San Francisco."

Medical Inspector A. Hocking, detached from President of Naval Examining Board.

Asst. Surgeon and P. Crandall, promoted to be P. A. Surgeon Feb. 1, 1891.

Carl De Wolf Brownell, of Bristol, R. I., commissioned an Asst. Surgeon in the Navy April 1.

SPONTANEOUS UMBILICAL HÆMORRHAGE IN NEWLY-BORN INFANTS.

Read before the Medical Society of the District of Columbia, February 2, 1891.

BY J. WESLEY BOVEE, M.D.,

VISITING PHYSICIAN TO WASHINGTON ASYLUM HOSPITAL; ATTENDING PHYSICIAN TO ST. ANN'S INFANT ASYLUM; AND OBSTETRICIAN TO COLUMBIA HOSPITAL FOR WOMEN AND LYING-IN ASYLUM.

The subject of hæmorrhage from the umbilicus and umbilical cord of infants during the first few days after birth has received very little attention from the profession. And I am led to think this condition has not received the amount of consideration it deserves. It is fortunately of infrequent occurrence, and having seen four cases, I have ventured to prepare this paper upon that subject.

Any malady having a mortality rate of 76 per cent., occurring ever so seldom, should command more earnest attention from the medical profession than is shown by the literature upon this grave condition of the newly-born. It should not be cast aside with but superficial consideration; it should be carefully studied. In this paper I have considered only the variety of omphalorrhagia in which there are usually manifestations of a general condition.

The seventeenth century brought us the first allusion to this subject, since which time various writers have occasionally written upon it. Probably the first case of this trouble ever recorded in medical annals was that published in the work of Philipp Hoechstetter, of Augsburg, in 1635. The victim, a boy, was thought to be suffering from hæmophilia. According to my researches the next was the fatal case of Mauriceau, in 1668. Next following this was the case of Watts, in 1752, so frequently quoted by recent writers as the first recorded case, and following it, Degland's case. These reported cases comprise nearly all the literature on the subject to 1800. Cheyne begins the work for this century by reporting a case in 1801, and four years later Sedillot's excellent article appeared. In 1822 Pout reported three cases, and since that date over 500 cases have been reported. A number of valuable contribu-

tions to this subject have been furnished by Marc Buchner, Rittershain, Ribemont, Granddier, Jenkins and others, and to these writers I have to acknowledge my indebtedness for much information received from their papers. I have also to thank the officers of the U. S. Army Medical Library for their kind assistance.

Frequency.—If by considering the number of reported cases an opinion as to its frequency can be formed, surely it is a very rare occurrence, for since the memorable first case published by Hoechstetter in 1635, but 518 cases of this kind of hæmorrhage from the umbilicus of the newly-born child have been published. Previous to 1850 this subject was scarcely mentioned by textbooks on diseases of children and obstetrics. Since that date those that mention it pass it over as of little moment because of its rarity. During the years 1851 and 1852 nearly 10,000 children were admitted to the Foundling Hospital in Paris, there being but one case among this large number of children. Vogel says it occurs once in 10,000 cases, he, in a large experience, having seen but one case; and according to Dr. Stephen Smith, there were among 6,654 births in the Dublin Lying-in Hospital, no cases of this trouble.

Minot says: "It is not a little remarkable that men of such large experience as Churchill and West should barely allude to this subject." West's work on Diseases of Infancy and Childhood, contains the results of 640 observations, chiefly made among 16,276 children who came under his observation. He never met with a case. Other writers, however, claim for it a much greater frequency. Cox reported two cases among 2,000 births at the Emigrants' Refuge, Ward's Island, New York, and Dr. E. L. Partridge says that among 1,166 infants born in the Nursery and Child's Hospital in New York, eleven cases of hæmorrhage from the umbilicus occurred, with a mortality of 75 per cent., and that in the Sloane Maternity Hospital fourteen cases, with a mortality of over 60 per cent., occurred among 850 infants. He has seen over thirty cases, but writes me he has no notes of them. Whitall, writing on this subject in 1877, said that during the last preceding twelve years 2 per cent. of the infants born in the Colored Hospital in New York had suffered from this malady. Dr. Julia Ingram had

three fatal cases at the same time in one ward of the New England Hospital. The greatest number of cases seen by one practitioner were the 132 cases of Rittershain. If its occurrence be rare, what must have been the experience of a man who has seen 132 genuine cases. I cannot believe it is so rare. On the contrary, my experience is that it is much more frequent than supposed, probably occurring as often as once in 500 cases, and I believe it figures largely as a cause of death among infants. The health office reports of the large cities should show valuable figures on this subject.

Causes.—The causes of this form of bleeding are numerous and varied. If the cord has been short, considerable traction may have been made upon it during labor, and slight solution of continuity of the tissues about the umbilicus may have been produced, though perhaps escaping notice for some time. It may also be commenced by injury, as cited by Willis,¹ causing alarming hæmorrhage, but usually arises spontaneously. Another frequent exciting cause is the formation of granulations at the umbilicus following the dropping of the cord, as in Read's² case, which readily yielded to the application of benzoated oxide of zinc ointment. Deformities of the viscera have been considered in this connection, inasmuch as they have been frequently found in patients that have died from this cause.

Some writers have thought climatic conditions of various kinds have been influential as a cause, but I think without tangible reasons.

Sex was pointed out by Ray,³ in 1849, as being important in this connection, as two-thirds the infants affected were males.

The most prolific causes are hereditary diseases, such as syphilis, hæmophilia, etc., and dyscrasia either local or constitutional. Grandidier⁴ states that out of 576 bleeders, spontaneous hæmorrhage from the umbilicus occurred in but twelve cases, but some of these twelve cases were not newly-born. In fact, fatal bleeding in this class of people does not usually occur until after the first or second year, and the blood is usually coagulable, in contradistinction to the condition of the blood in the malady under consideration.

There can be no doubt that syphilis is a frequent cause. Campbell's⁵ case, the mother of which did not know who was the child's father, and who had previously been under treatment for syphilis by Dr. Campbell, is a striking case. The child seemed at two months to thrive upon large doses, 5 to 8 grs., of iodide of potash four times daily. In cases one and three of the author's, syphilis also seemed to have acted as a cause.

In Ingram's cases the cord was not ligated just

after birth, as is customary, which possibly may have acted as an exciting cause, inasmuch as three of them occurred at the same time in the same hospital ward.

Dr. Minot⁶ published cases which bear very strong evidence of heredity. He quotes Dr. A. Hoover, of East Cambridge, who says: "I attended a woman to all appearances healthy, and who has good labors. She has lost four children from umbilical hæmorrhage. She has since had a child which presented a slightly jaundiced look, but no hæmorrhage took place and it did well."

Minot has also had cases in which the first, a female, and fourth, a male child, had died from this cause, and the second and third children were healthy and escaped umbilical hæmorrhage. He found that in 11 out of 12 cases, or 91 $\frac{2}{3}$ per cent., the mothers were healthy; that in 26 out of 32 cases, or 81 per cent., the children were born healthy; that in 22 out of 32 cases, or 68 $\frac{3}{4}$ per cent., the children were males; and that in 14 out of 15 cases, or 93 $\frac{1}{3}$ per cent., the labors were natural. It could readily be understood if hæmorrhages of this character would be most frequent in poorly developed and feeble children, but most cases have been reported as being in good condition and of good weight.

Another cause that is worth noticing is the mental condition of the mother during pregnancy. This may be bordering upon the subject of maternal impressions, but the two have actually been merged. In one of Minot's cases the mother had worried continually during pregnancy lest the child should be a victim of hæmorrhage from the cord, and this after having a number of children none of which was so afflicted. If the mother has been subjected during pregnancy to uncomfortable and improper hygienic surroundings, and is in bad general health from any cause, the infant will be more liable to this unfortunate condition.

Symptoms.—Bleeding about the navel usually appears without warning, though in occasional cases it is preceded by more or less marked jaundice, purpuric spots, as in one of McCarty's⁷ cases, ecchymoses, petechiæ, and perhaps bleeding from other parts, as observed by Dr. Julia Ingram.⁸ Granulations at umbilicus should cause us to fear this malady. Although nearly all the children that have been afflicted with this trouble have been in good condition, yet it is believed that premature birth, as in two of the author's cases, may predispose to it. The various evidences of syphilis, and of purpura and kindred affections, when present should give us alarm. One of Ingram's cases was noticed to have a peculiar whining cry accompanied by paralysis of left side of face. In Gibbs's⁹ case the mother stated she

always bled easily and at the slightest provocation. She had severe post-partal hæmorrhages. These two facts should have aroused anxiety concerning the child. Very frequently the only symptom noticed previous to the hæmorrhage from the umbilicus is jaundice, which is often quite marked, but clayey stools usually accompany it. Usually the first indication of this form of hæmorrhage is the bloody appearance of the dressings over the umbilicus, which, according to the amount of blood lost, is more or less marked. This may occur at any time. In fact, one case was reported in a young lady who had frequent attacks of bleeding from the umbilicus since infancy, but Minot found in 47 cases that the average age at which it began was eight days. It may be a very slow oozing, continuing several days and yielding to treatment, or ending in death. Or it may be sudden and severe, like Young's¹⁰ case, which ended in death in twenty minutes, and that of Stephen Smith,¹¹ which died in one hour.

Some cases have been reported where the hæmorrhage was slight and of brief duration, recovery soon following. Unfortunately, these cases are but a small part. The bleeding may occur previous to separation of the cord, and in that case is usually severe, and generally fatal. Of the last 37 cases reported I began bleeding before the cord separated. Of these 14, or 74 per cent., died. And of 18 in which hæmorrhage occurred subsequent to that event only 7, or 39 per cent., succumbed. It would appear that most cases occur at the time of or subsequent to separation, as the cord usually separates from the fourth to the sixth day, and Minot's average for the beginning is the eighth day.

There seems to be some relation between jaundice and this malady, and Dr. Brooks,¹² of Texas, reports a case of profuse escape of bile, itself, from the umbilicus. In some cases there is diarrhoea, and in others constipation. Very frequently, after the loss of blood has gone on one or two days, hæmorrhage from the bowels, eyes, skin abrasions, roof of mouth, gums, etc., occur. Partidge¹³ has found, also, blood in the vagina, and by post-mortem examinations, blood in the uterus. One of Ingram's cases vomited blood. Vomiting, however, very seldom occurs, and pain was noted in but four cases. In these cases it was attributed to extending the legs. Petechiæ and ecchymotic spots on different portions of the body occur frequently during the progress of the malady. They are most frequent on the back, forehead, roof of mouth, knees and elbows. Minot found these conditions in twelve out of thirty-nine cases. In Campbell's case, which was much emaciated, there were bullous syphilides. The

hæmorrhage, when rapid or profuse, comes usually from the arteries and is lighter in color than when it merely oozes from about the umbilical pit. In Young's case which died so quickly, the hæmorrhage was from the left side of the base of the cord, and Clandy's was of the same character. Quite a number of patients have died in convulsions. After the bleeding has progressed in spite of treatment, one or two days, the infant shows marked lowering of vitality, nurses feebly, moans, appears pallid and emaciated, and perhaps dies though the hæmorrhage be arrested. Bulging of the fontanelles is frequently present, and the presence of fluctuating tumors about the head has been observed. The blood is usually thin and watery, and varying in color from very pale to very dark, when it is thought to contain bile, as it stains the clothing the same as bile would if brought in contact with them. It usually oozes from the umbilical depression and is non-coagulable. The average duration of this form of bleeding cannot be definitely determined, as the length of time bleeding continues is not usually reported in the successful cases. Rouse says the average length of hæmorrhage in fatal cases is three and a half days. The fortunate cases probably bleed considerably less and a shorter time.

It has been my misfortune to meet with four cases of this fatal condition, and but one of them recovered. I give them in detail below. Two cases were seen by my friend, Dr. H. M. Newman, of this city, who has kindly furnished me notes of them which are appended to my own cases.

Case 1.—Carrie C., colored, single, age 16 years, an inmate of the female workhouse in this city, was seized with pains in lower abdomen, with hæmorrhage from uterus, during the month of March, 1890. In this institution there is a daily average number of about 120 women—the refuse of the District of Columbia. The patient, Carrie C., though better than the greater portion of her associates, was not a brilliant in the moral world, and upon inquiry it was revealed that she had not menstruated during the past six months. She was transferred to the Washington Asylum Hospital, where upon examination she was found to be pregnant about six months, and was kept in bed five days, taking opium to the extent of narcosis for the first two or three days. After being about the ward she complained of pains and lost a little blood. She was treated nearly the same as during the first attack. After this she felt very well for a few weeks, when another attack occurred similar to but not as severe as the former attacks. I suspected she was attempting to relieve herself of the fœtus and had her constantly watched. She was tidied along until the night of June 4, when labor began in earnest, and she was delivered at 8 A.M., the 5th, of a healthy male child weighing 8 lbs., nothing un-

usual occurring. During this and the following days the child voided urine and its bowels moved, nothing unusual being noted by nurse concerning either act. At 4 P.M. the 6th the nurse reported bleeding from the cord. A second ligature was placed around the cord near the abdominal wall and the bleeding ceased. At 11 P.M. bleeding was again observed and a third ligature was applied, still lower than the second one. The flow ceased, but in a short time oozing from about the junction of cord and abdomen was noticed. A concentrated solution of tannin was applied and again the hæmorrhage ceased, to reappear in a few minutes. Collodion was now used, which checked the oozing for about fifteen minutes, but the respiratory movements of the child cracked it and the flow resumed. Monsel's solution was freely applied, but with little avail, the child dying at 12:30 A.M. the 7th. There were no symptoms other than bleeding.

Autopsy at 9 A.M. June 7. Rigor mortis not well marked, muscles pale and soft, heart contracted; umbilical vein large, as were the hypogastric arteries. A clot about 3 inches long and 1 inch broad was found on right side of abdomen, with deep staining of peritoneum beneath and around it. Other extravasations of blood were found in both the visceral and parietal layers of the peritoneum. All the visceral organs pale and soft. The next three cases occurred in the Columbia Hospital for Women and Lying-in Asylum during my services there, and through the kindness of Drs. Scott and Kelly I am able to give them in detail. They are as follows:

Case 2.—Mary L. C., colored, age 20 years, was admitted to hospital December 16, 1885, pregnant the first time. Her general appearance was excellent, and she could remember no symptoms of pregnancy other than morning sickness during the early months. Urine contained no albumen. Fœtal heart sounds, 140 per minute, heard to the left of median line. Labor began December 18 at 6 A.M., and progressed slowly and normally until the 19th at 10 P.M., when she was delivered of a colored living, female child weighing 5¼ lbs., and healthy to all appearances. The placenta appeared normal and was expelled intact, weight 1¼ lb. On the second day after birth a slight hæmorrhage occurred from the cord, which yielded to a compress and a second ligature. On the fourth day another attack occurred that was also treated successfully by the same method for a time, but at 2 A.M. the 23d, a fresh fatal hæmorrhage began and lasted but a few minutes. The hæmorrhage was always sudden and without warning.

Case 3.—P. A., a prostitute, was admitted about 1 P.M. January 29, 1887, in labor. She was white, thin in flesh, anæmic and of a nervous temperament. About two months previously I had attended her for threatened miscarriage, she de-

claring it her first pregnancy. She was put in bed, and an examination revealed a fooling presentation, the sacrum to the right and front. The labor was rapid and easy, and at 3:20 P.M. she was delivered of a male, white child, weighing 4¾ lbs., in good condition but probably premature. Milk was secreted sixty-three hours after delivery, but she refused to nurse child and secretion was arrested in a few days by application of spirits of turpentine. The child was wet nursed. Considerable hæmorrhage occurred from the umbilicus on the seventh day, February 5, which could not be arrested by pressure and persulphate of iron. It was transfixed with hare-lip pins, ligated and covered with plaster of Paris. This permanently checked the oozing of blood. Three days later the pins were removed. After the hæmorrhage was arrested the child improved rapidly, and was in an excellent condition when it left the hospital with its mother about two weeks later. It was farmed out that summer, and was buried before the hot weather ended. The mother is yet a thin, nervous woman, bearing evidence of syphilis.

Case 4.—Eleanor M., black, 21 years old, was admitted to hospital in labor December 13, 1887. This was her first child. She menstruated last April 1, and felt life in July. She had suffered almost continually from vomiting since conception occurred, and headaches during her pregnancy were severe and frequent. Labor pains were feeble and cervix uteri was not dilated until 3 P.M. The second stage was very rapid. The head had just begun to bulge the perineum slightly when a hard pain came on. The patient now became unmanageable through fright and, bearing down hard, drove the child through the perineum into the world. The placenta, weighing 1¼ lb., immediately followed without another pain. Part of the membranes were, however, firmly adherent, and had to be peeled off manually. Severe post-partal hæmorrhage occurred. Notwithstanding this the perineum was closed by sutures and union procured. The child, a male, was very light-colored as a negro child, and from its appearance was thought to be three or four weeks premature. Slight œdema of left eyelids appeared December 20, which was attributed to child frequently rubbing them with fists; hands were tied; mild sol. alum and zinc dropped in eye every two hours and lids smeared with vaseline. Eye recovered in three days. December 27. Baby nurses regularly, but seems to be suffering from malnutrition. Bowels loose and feces of grayish color. Ordered beef peptonoids and hydrarg. cum creta gr. ʒss, with bism. subnit. gr. ij., diarrhœa ceased entirely December 28, after taking twelve powders. December 30 diarrhœa began again; urine very high-colored, powders renewed; spts. æth. nit., gtts. v. every two hours. There appeared considerable oozing of blood from um-

bilicus, which was touched with liq. ferri sulph. and a compress applied. Hæmorrhage persisting, styptic cotton was used and the stump touched several times with the iron solution. The blood persistently oozed under the compress, being very dark, as thin as water and non-coagulable. Several times during the night bleeding was very profuse, but would entirely cease for a few minutes whenever the dressing was renewed. The skin was extremely yellow, jaundice being well marked. Gums bled upon the slightest touch. Patient grew weaker as hæmorrhage continued, until, about 9 A.M. December 31, it died of exhaustion.

The next two cases occurred in the practice of Dr. H. M. Newman of this city, who communicated them to me. He was called during the year, 1885, to see a fairly plump female child that had been delivered by a midwife and had progressed well until the fourth day when hæmorrhage from the umbilicus began. The oozing continued, and on the third day, being the seventh since birth of the child, he was first called to see it. He found the cord had sloughed off and blood welling up from the umbilicus. He applied persulphate of iron under a compress and later nitric acid. These failing, he ligated *en masse* which checked the flow for a short time only, and the child died the following night. The other case he saw during the month of September, 1890. A healthy male child ten days old was attacked by a sharp hæmorrhage from the umbilicus which yielded to one application of a styptic covered by a compress. No recurrence of the accident was noticed and the child is now well.

Prognosis.—The gravity of this malady is under the most favorable circumstances very great. The result seems to be most favorable when the infant is of the female sex, born of good parents, the mother being in good health during the term of pregnancy; when the general condition of the child is at or above par, the bleeding slight and occurring at an advanced age of the child. Of course any malformation of the viscera would tend to a fatal termination. But marked jaundice with persistent oozing of blood from about the umbilicus are very alarming phenomena, and if hæmorrhages from other parts set in, purpuric spots appearing, the result will be fatal in nearly every case. Occasionally a slight, short hæmorrhage from the umbilicus, even in vigorous children, will cause such a depression that reaction never occurs and the child dies. I think, however, that in infants suffering from marasmus and kindred affections in which their vitality is low, that an attack of even slight omphalorrhagia proves fatal. Altogether the mortality rate in this malady is gradually decreasing. As given by Jenkins in 178 cases it was 84 per cent. Hennig¹⁴ says it was 83 per cent. in 230 cases, includ-

ing Jenkin's table, and Keiller, adding six cases to Hennig's list, says it is 68 per cent. while the author finds in 518 cases it is 76 per cent. Hennig says one-half die on the fourth day and 83 per cent. do not live beyond the second week.

A few, however, live longer before death overtakes them. Olliffe's case died at the end of seven weeks, being the longest case yet recorded. His patient was small and delicate and on the sixth day the cord separated. Five days later omphalorrhagia began, accompanied by icterus, purpuric spots on tongue and palate and bloody dejections. The oozing was soon controlled by ligature *en masse* but great debility continued until death occurred. Of the 518 cases reported 393 cases died and 125 recovered,—a mortality of 76 per cent. Of these cases the sex is given in but 347 cases, 224 of which were males of which 174 died, 78 per cent., and 123 were females, 95 of which died, 77 per cent. Of the 169 cases in which the sex was not given 124 died, a mortality rate of 73 per cent. The male sex is afflicted about twice as often as the female.

Pathology.—The pathological conditions existing in umbilical hæmorrhage in the newly-born has received very little attention and so far the microscope has had very little acquaintance with this subject, although Vancott, of Brooklyn, did some careful work on the subject. The diseased conditions found have been variable, and again cases have occurred in which no lesion was found. In a number of autopsies on infants that have died from this trouble the umbilical vessels have been found closed and in others patulous, which in early cases is not necessarily pathological.

M. Lorain, according to M. Henri Roger,¹⁵ while a student at *Enfants Trouvés*, investigated extensively the process of obliteration of the umbilical arteries and arrived at the following conclusions. There are two modes of obliteration: in the first the obliteration is provisional; it suffices for the present necessities of the new-born child and guards against early accidents; it consists in a clot which forms a few hours after birth. This coagulum is found in children who have not lived more than four or five hours; it commences sometimes in the arteries of the cord, and sometimes at the junction of these vessels with those of the abdomen; it is black, of mediocre consistence, adhering but slightly to the walls of the artery, and is at first very short; subsequently it is elongated by the successive deposition of new molecules, until, at the end of the second day it occupies two-thirds or half the length of the artery, commencing at the umbilicus. It is then firmer, denser and more adherent to the walls of the vessel. During the succeeding days this coagulum acquires greater consistence and loses at the same time, its black color and assumes a fibrinous aspect;

¹⁴ Keiller A. *Edinburgh Med Jour* 188 and 189: xxvi, 203.

¹⁵ *Lond. M. Times*, 1887, p. 177.

¹⁶ *L. Union Med.*, 1887, 128-147.

becomes more and more regularly cylindrical. In proportion as the coagulum contracts the artery narrows. This may be called the provisional mode of obliteration. The other consists in the complete occlusion of the artery at its umbilical extremity, and occlusion which occurs in the following manner: The extremity of the artery is retracted from the navel, contracts, and presents a conical extremity; this hardly takes place before the twenty-fifth or thirtieth day; at this date the calibre of the artery is very small, and is occupied by a fibrinous clot, white, dense, regularly cylindrical and closely adherent to the arterial coats. This is the true obliteration.

Keiller found in a case that began bleeding on the eleventh day and died on the fourteenth, that the umbilical vein and left hypogastric artery were empty and firmly contracted, while the right hypogastric artery was open and contained traces of blood. A very plausible cause of this trouble and a condition usually present in it is inflammation of the umbilical blood vessels. By thickening and stiffening the walls of these vessels it prevents contraction of them and consequently encourages bleeding. There seems to be, however, no constant condition of the blood vessels of the navel in this malady. In one case in which the arteries and vein were both found pervious and pus and blood clots were adhered to the tunica of the veins. It is reasonable to think these vessels should close shortly after birth as in the lower animals where the cord is not tied and hæmorrhage does not occur. I believe that when these vessels are found pervious after a week it is due to a non-coagulable state of the blood and is pathological. In cases of bleeding after separation of the cord there are usually found ulcers at the site of detachment.

The most constant condition found is some functional trouble with the liver—some derangement with the formation and elimination of bile. Jaundice and clayey stools would naturally indicate obstruction to the passage of bile into the alimentary canal and this really is true in many cases. Thayer¹ found in a case an empty gall-bladder and an impervious condition of the lower half of the bile duct and the whole of the ductus communis choledochus. In about half the autopsies the bile duct was found occluded. Many different phrases have been used to express the but little altered condition of the liver in this malady. Van Cott² found by the microscope that in a case examined by him the cells of the parenchyma of the liver were quite uniformly swollen, granular, contained bile pigment and their nuclei quite indistinct or invisible. The connective tissue of the portal canals was everywhere increased and densely infiltrated with small round cells. This indicated hepatitis which no doubt caused

the jaundice and secondarily the hæmorrhage on the 6th day which ended fatally on the 11th day.

The condition of the blood, no doubt, plays an important part in umbilical hæmorrhage. If over-loaded with bile it is rendered non-coagulable by its extreme alkalinity and the red blood corpuscles are to some extent destroyed. The walls of the vessels are consequently weakened and the fluid blood escapes more easily than usual. The extreme fluidity of the blood of infants suffering from bleeding from the umbilicus has been considered due, by some writers, to the mothers drinking large quantities of water during pregnancy thus diluting their own blood and of course that of the child. The changes in the circulation of the blood at birth are not always perfect and these imperfections tend to nonaeration of the blood. In consequence venous blood is carried back through the arterial system to the tissues of the body and vitiation ensues. With that comes, also, weakening of the blood vessels and probably loosening of the provisional clots in the umbilical vessels. This loosening permits bleeding from these vessels varying in amount according to the extent of loosening and if the blood be much thinned by loss of red blood globules and by dilution with bile the tendency of the flow is to continue. Various malformations have been found in the circulatory system in these cases. Ingram found a very small right ventricle of the heart and no septum between its auricles. This child lived fourteen days, four days after the hæmorrhage began, which continued until death ensued. There was bleeding at other points, vomiting of blood occurring twice and the post-mortem examination revealed two stomachs, both filled with deorganized blood.

Keiller found the ductus venosus, ductus arteriosus and foramen ovale, all open in a child that died on the fourteenth day after four days of uncontrollable hæmorrhage. In many cases a tendency to bleeding is shown by constant dribbling of thin non-coagulating blood from very slight scratches on various parts of the body. These anatomical defects must seriously interfere with the proper circulation of the blood and decrease its oxygenation. It can be readily understood how the venous system would become engorged and blood back up into the umbilical vein, dilating it where it had nearly closed and escaping at its delicately closed extremity. Again some inherited disease may have effected the wall of the blood vessels. This was noticed in a number of cases where such condition was almost certain to have existed and the blood being very fluid and deficient in fibrinogen the flow was free. Hæmorrhages also occurred from the gums, eyes, bowels, stomach and other parts.

In the author's first case there were numerous extravasations of blood in the peritoneum and a large clot was found in the abdominal cavity.

¹ N. Y. Med. Jour., 1855, xlii, 434.

² Brooklyn Med. Jour., 1855, i, 219-229.

Effusions of blood have also been found in the lateral ventricles and under the arachnoid. Other organs have been found at fault in these cases. Hennig states that in every case there are uric acid infarcts in the kidneys. Melena is a very frequent complication of the form of hæmorrhage under consideration, probably due to the same cause. Zeigler² says backing up of blood into veins, the walls of which are diseased, is usually the cause of this condition, and Klebs³ and Eppinger⁴ have described a micrococcus found in this malady which they called *monas hæmorrhagicum*.

To be concluded.

REMARKS ON THE TREATMENT OF PROLIFEROUS INFLAMMATION OF THE MIDDLE EAR.

Read before the Northwestern Wisconsin Medical Society, at Neenah, London, July 5, 1890.

BY H. V. WÜRDEMANN, M.D.,
OF MILWAUKEE, WIS.

Chronic non-suppurative inflammation of the middle ear has been well divided by one of our American writers into two great classes (St. John Roosa):—

CATARRHAL AND PROLIFEROUS.

Politzer and Gruber accept the same classification but under different names.¹ Others subdivide these terms, giving each a local habitation according to its most conspicuous lesion.

By *proliferous* disease is meant that form of chronic non-suppurative catarrh in which there are marked changes in increase or hypertrophy of tissue,² attended by little or no fluid secretion, *i. e.*, a dry catarrh (Roosa.) This disease is characterized chiefly by its insidious course, having little or no symptoms beyond gradually increasing deafness and tinnitus aurium. It eventuates in entire sclerosis (hence the name given to it, by some writers, of "sclerosis of the middle ear") and profound deafness. The tinnitus may indeed be the only symptom of which the patient may complain. He may indignantly refute the idea that he is at all deaf and only seeks the removal of the obnoxious subjective sounds. The pathology of this affection has been well displayed in several well known text-books. I wish to make a few remarks on the methods of treatment that in my experience have been found to afford the most relief.

Proliferous inflammation having acquired a foothold in the ear, as it were, is in some cases

practically incurable, and the patient should be satisfied if the disease is but kept in check by the treatment. Without proper care the affection is invariably progressive, going from bad to worse and lasting the lifetime of the patient. Thus the prognosis should be always a guarded one, and the patient should be acquainted with the course and nature of the disease in order that his coöperation may be secured and that he may not become disappointed with the length of the treatment. One or two, or a half dozen sittings, in some cases, accomplishes little or nothing. The amount of good that can be done may only be determined by a week or ten days' trial. There are some cases in which, within certain restrictions, an absolute cure may be promised. After a course of treatment by which the hearing has been restored and the distressing tinnitus removed, the patient should be warned that a point of less resistance has been formed which will again give way before a succession of colds and induce a return of the trouble. Those patients who are so fortunate as to recover must observe the strictest rules of hygiene, and should return under the care of their medical adviser at the slightest ear symptom. As a general rule they should be counseled to return in the spring and fall of the year for examination, and if necessary, for a course of treatment.

Do not think this a too gloomy view of the matter, others have given worse.

Although we cannot in all cases guarantee a cure, yet we may lift many up from the slough of despond into which they have been plunged by their deafness and the agonizing annoyances of the accompanying tinnitus. Yea, we may, if it is allowed, save some from the madhouse. Many persons have been reckoned insane by reason of hallucinations of hearing caused by tinnitus, and some have even been cured of "brain disease" by treatment of the ears.³

The deaf, with the exception of deaf mutes, are proverbially sullen and morose. By lifting however so little their load of affliction we may restore those to the world who have retired within themselves, and render them agreeable neighbors and thankful patients.

The therapeutic measures at our disposal are the following:

1. Local treatment of the middle ear and Eustachian tube:

1. Inflation by Politzer's method: *a*, with air; *b*, with vapors.
2. Inflation by catheter: *a*, with air; *b*, with steam; *c*, with medicinal vapors.
3. Injection of fluids through catheter.
4. Eustachian bougies.
5. Electricity.

6. Methodical use of ear trumpet and Siegel's otoscope.

7. Operative treatment.

8. Symptomatic treatment of tinnitus and vertigo.

II. Local treatment of nose and fauces.

III. Constitutional treatment.

The local treatment of the middle ear and Eustachian tube is of course the most essential. Often the disease is circumscribed and it is this class of cases that yield most readily to the local applications. Although the topical applications are used through the Eustachian tube they are not, as some writers would have it, entirely directed to that appendix. The vapors and fluids used do undeniably reach the cavity of the tympanum, as is evinced by an inspection of the drum after using them.

Atmospheric air is of great importance, as the simple use of it, either by Politzerization or by the catheter, restores the equilibrium of the air pressure on either side of the drum, and the force of its entrance breaks up adhesions and drives out accumulations of mucous, and besides all this, is a valuable means of diagnosis. The gain in hearing distance (H. D.) after the first inflation, while not so marked as in the strictly catarrhal forms of middle ear disease, is frequently so great as to give the patient undoubted confidence in the physician.

Chloroform, ether, bromethyl or iodine crystals may be used in the Roosa bulb inhaler. The first named is of value in determining, in doubtful cases, whether the tympanum has been reached by the inflation. This point is shown by an injection of the blood-vessels at the handle of the mallus, caused by the irritation of the vapor, and an enlargement of the light spot.

Where sclerosis exists a sensation of heat will be felt by the patient in the ear after the inflation of the same by any of the three first named, while in a healthy ear the sensation is that of coldness. This may be considered a valuable aid in both diagnosis and prognosis.⁵

Where decided retraction of the drum is present (Figs. 1 and 2), or where spots of atrophy occur, a great change will be seen after inflation. (Figs. 3 and 4.)

Treatment through the catheter is our mainstay in proliferous inflammation. The vapors which have been advocated have resolved themselves into three. The vapor of water (steam), although an old remedy, is sometimes useful where deficient secretion exists.⁶

For the exhibition of this remedy I use an ordinary steam atomizer to which is attached a bottle with three glass tubes in the cork for the

purpose of catching the water of condensation and to connect the propulsive power. (Fig. 5.)

Fig. 1.—Great retraction of drum with chalk in membrane.

A rubber catheter must be used as metal becomes too hot. One must be certain that the end of the catheter is in the tuba Eustachii, or damage may be done. To that end steam should be used only when a well-developed sound is heard through the otoscope on auscultation when

Fig. 2.—Same after inflation with chloroform.

the ear is inflated with air. The steam should be conducted to the ear by successive puffs permitting the catheter to cool between each interval. The sitting should last from five to ten minutes three to four times a week.

The vapor of camphor and tincture of iodine is a more convenient remedy and accomplishes the purpose of steam, that of local stimulation, and is applicable to the great majority of cases. It is employed in the apparatus shown in Fig. 6. This remedy was suggested by Roosa.⁷

Fig. 3.—Partial atrophy of membrana tympani.

The sitting should last from two to five minutes daily. Where considerable effect is desired this treatment may be preceded by steaming.

⁶ L. J. Pardee, Transact. American Otological Society, 1870. Roosa, "Diseases of the Ear," p. 366.

Nascent muriate of ammonium (first suggested by Moos, of Heidelberg), is of high value where irritation is required, in those cases that do not respond to other treatment.*

Fig. 4.—Same after inflation with atmospheric air.

The apparatus that I use for the purpose of conveying this vapor to the ear is shown in Fig. 7. It consists of a test tube holding a small quantity of muriatic acid enclosed in a bottle half-filled with water, to which has been added a few drops of strong aqua ammonia. The two are connected as per illustration.

The sitting should last from two to five minutes daily, the patient taking care to breathe none of the irritating vapor.

Fig. 5.—Apparatus used for steaming the Eustachian tube and middle ear.

In using each of these apparatus the catheter is either held in place by the left hand of the surgeon or by the patient, or a pair of nose-nippers may be employed. The best of these is composed of a strip of whalebone folded upon itself; this was first used by Delstanche. (Fig. 8.)

All apparatus figured in the foregoing is easily made by the physician himself.

Fig. 6.—Apparatus for generating the vapor of camphor and iodine. (Roosa.)

The German authors are firm believers in the efficacy of fluid injections through the Mastachian tube into the tympanum. This treatment, in my opinion, is useful in some cases in conjunction with other methods. The ordinary way is to inject a few drops of the desired fluid (warmed) into a catheter after insertion, and then to forcibly blow into the same by the air bag. Doubts have been expressed as to whether the medicine ever gets farther than the mouth of the tube. If the patient is instructed to swallow during this procedure, the fluid usually gains the tympanic cavity. The elastic catheter of Weber may be used and the fluid pushed forcibly beyond the isthmus tube and into the tympanum. This method, however, is dangerous, and should be, if at all, carefully done. Evidences of success may be

Fig. 7.—Apparatus for generating nascent ammonium muriate.

noticed by the patient feeling a slight pain, which passes away in a few moments, and a feeling of fullness and deafness, which exists for some hours, when some benefit from the procedure may be expected. This treatment attains its best results when used about three times a week.

Numerous ingenious and complicated instruments have been devised for making these injections, but in my opinion, simply the catheterization and swallowing are essential.

Fig. 8.—Catheter holder

It is advisable to treat patients by either of the previously described methods not longer than two months at a time, when an interval of at least a

† Politzer, Lehrbuch, p. 62. Troltsch on the Ear, p. 228.

month should intervene before treatment is again renewed by the physician. During this time a Politzer bag with the inhaler may be used by the patient, who should be instructed to blow up the ears once or twice a day according to the indications. Iodine crystals or ether and chloroform may be used in the inhaler.

The following procedures are of occasional use in special cases. Eustachian bougies are indicated where an insufficient current of air on inflation by the catheter reaches the tympanum. (This can only be determined by the use of the auscultation tube or otoscope.) They are strongly advocated by Urbantschitsch, of Vienna, who lays down a number of indications for their use. It is but seldom that we must have recourse to them. The catheter is first passed and then the bougie is pushed up as far as the isthmus (24 mm.). It is allowed to remain *in situ* four to five minutes and then is withdrawn. The end of the bougie which had rested in the tube after withdrawal should present the shape of a lengthened letter S. Afterwards the ear should be gently inflated by the air bag. If the bougie has caused

Eustachian catheter with a copper wire running through it. The catheter with the wire drawn inside is introduced in the usual way and the wire being held firmly the catheter is withdrawn one half inch leaving wire in the tube. The current is now turned on until the burning feeling is as great as the patient can comfortably bear and continued from five to ten minutes.¹² My experience with this method has led me to attribute any apparent increase in hearing distance during the use of this agent rather to the effect of suggestion than as the result of the current.

Systematic use of the hearing trumpet is in the profoundly deaf not alone an aid to hearing but may even prevent the extension of the deafness, and in some instances an improvement may be noticed under its use.¹³

Siegel's otoscope is not only a valuable aid in diagnosis, in the differentiation of atrophic spots and scars from perforations and in the determination of rigidity and adhesions, but is also of therapeutic value in breaking up the latter. By a course of local gymnastics with this instrument sometimes the hearing is improved.

Operative treatment is sometimes indicated al-

Fig. 9.—Division of the posterior fold.

pain or if upon withdrawal it should be smeared with blood, on no account should inflation be practiced. Emphysema and other grave accidents have occurred from neglect of this precaution, even in the hands of the most earnest advocates of this method.¹⁴

The good of electricity is doubtful, still judging from the effects of the galvanic current in other parts of the body, it may aid in the absorption of exudative masses. A recent writer¹⁵ advocates its use in proliferous disease as follows: "An electrode consisting of an insulated rubber speculum with a handle, through which speculum runs a conducting wire" is attached to the negative pole of the battery and used in the meatus, the latter being filled with warm salt water. "If the tube is pervious the positive pole is attached to an ordinary sponge electrode and pressed under the angle of the jaw of the opposite side. If the tube is not freely open the positive pole is attached to an electrode consisting of a hard rubber

Fig. 10.—Incision for tenotomy.

though it seems that in this country at least it has fallen into disrepute.¹⁶

It is advisable in the following instances: An artificial opening may be made in the drum when the membrane is very thick or has much chalk deposit (Figs. 1 and 2), or where there is fixation of the ossicles, when an undilatable stricture of the tube exists, and finally when excessive tinnitus has not been controlled by previous treatment.

It is almost impossible to keep up an artificial opening for any length of time, as it soon closes over. The puncture of the galvano-cautery needle gives the best results. The application of chromic acid on the end of a silver probe, although a painful procedure, is sometimes successful in keeping up a permanent opening. Politzer puts a very small piece of hard gum tubing into the wound made by a paracentesis needle.¹⁷

Division of the posterior fold of the drum is in-

¹⁶ Lehtbach, p. 257.

dicated in excessive retraction of the same when inflation does not restore the natural position. It is done by the paracentesis needle in the position shown in Fig. 9.

Tenotomy of the tensor tympani muscle is done by a sickle shaped knife or the one that is commonly used for scarification. It is indicated in those cases where strong retraction exists, where the drum is restored to its normal contour and the hearing distance is markedly increased by inflation, but where a few moments later it is found that the original condition has returned. In some cases of the "telephone ear," (spasmodic contraction of the M. tensor tympani), which are not mitigated by rest and other treatment, it may be allowable to divide the tendon.¹⁵

This operation is again becoming fashionable and it is even being advocated by the continental authors as applicable to all "cases of sclerosis of the tympanum with relatively good bone conduction."¹⁶

I have noted two cases this year in which improvement was seen after this operation which was done on account of the first indication mentioned. The knife is entered one mm. behind the malleus between it and the stapes (Fig. 10), the blade being pressed upwards upon withdrawal.

In cases where ankylosis of the stapes exists, which have not yielded to previous treatment and where warranted by profound deafness and excessive tinnitus, the entire drum with the ossicles has been excised, or in other cases simply the ossicles.¹⁷

Where there has been adhesion of the membrane and malleus to the inner wall of the tympanum Burnett has excised the malleus and the membrane with good results in a case where this condition was accompanied by distressing tinnitus and vertigo.¹⁸

Trephining the mastoid, although practiced in previous years for this disease, is of course unwarrantable.¹⁹

The tinnitus and vertigo accompanying this affection is not always due to this disease alone. The deafness may also be greatly heightened by affections of other parts of the auditory apparatus, as for instance, disease of the labyrinth, of the nerve or even of the brain center. These structures are invariably affected after the disease has existed a length of time. The nerve and labyrinthine structures atrophy from disuse.²⁰

The treatment of the tinnitus and vertigo should be pursued on general principles and all sources of irritation should if possible be removed. Bromides may be exhibited, the effect being heightened by the addition of Tr. Cannabis

Indica.²¹ Morphine may be given when noises are paroxysmal.

No other sedatives have been found useful. Counter-irritation by a blister behind the ear will be occasionally of avail. Quinine has also been recommended in small doses. (Gowers).

The nose and pharynx, although usually in better condition than in that which obtains in the purely catarrhal form of inflammation, generally need attention, and the disease may not be deemed cured until these parts are in good order. I would especially refer to the removal of hypertrophied lingual or pharyngeal tonsils.

Of course constitutional treatment is here, as well as in other special affections, of prime importance. As is recommended by Sexton²² it has been my practice to administer minute doses of mercury for lengthened periods. The exhibition of strychnine is at times of value but upon its discontinuance the acuteness of hearing is again diminished. The disease is essentially a local complaint, being due to a combination of causes, arising as a rule from diseased conditions of the naso-pharynx. After it has existed for a length of time a change of climate does but little good except in the way of prophylaxis from colds.

The treatment through the catheter by medicinal vapors, especially the vapor of camphor and iodine, combined with the use of Politzer's method of inflation, seems to afford the most relief, and should be first tried. Some cases are helped by the fluid injections and in others a mixed treatment must be pursued. Of the operations advocated those of tenotomy and of division of the posterior fold prove the most useful. Operative treatment is, in the majority of instances, only a last resort.

305 Grand Ave.

VOICE IN FEMALE SINGERS AFFECTED BY GYNECOLOGICAL DISORDERS.

BY CARL H. VON KLEIN, A.M., M.D.

OF DALLAS, TEX.

I am requested by a well known ovariologist to state my observation of the voices of female singers when affected by gynecological disorders, hence the following is a brief statement of my observation.

The most difficult cases the laryngologist has to contend with are diseases of the throat caused by disturbance of the ovaries. It is a common thing to meet with cases of acute inflammation of the tonsils, larynx, pharynx and fauces in females during their menstrual period. I have observed the voice in many professional choir singers who have applied to me for treatment during the

menstrual period, defective in gravity, force, and timbre, producing in many cases a husky sound, as of a low, masculine order.

A laryngologist of acute hearing who will train his ear to the recognition of sounds and acquaint himself with a known voice, can detect a menstruate nine times out of ten. It is a known fact that all prima donnas try to avoid engagements during their expected period. It is a recognized fact from time immemorial that extirpation of the testicles will greatly change the voice in males. Unto this day the operation is practiced in some parts of the civilized world.

The finest male chorus I ever heard was by a band of eunuchs at the Alexandre Nefsky Church at St. Petersburg, Russia, who were prepared for that purpose. Born eunuchs, or hermaphrodites, generally have voices of feminine order, but do not make good singers on account of their sluggishness and want of animal propensities. It is said in order to make a good singer one must be in love. It is undisputable that impediment in the male organs influences the male voice, so, too, impediment in female organs influences the female voice.

In many cases of ovarian disturbance, enlargement and hypertrophy of the tonsils and of the soft palate are observed, hence the laryngologist oftentimes can accomplish but very little without the assistance of a competent gynecologist.

MEDICAL PROGRESS.

Therapeutics and Pharmacology.

CANTHARIDINATE OF POTASH IN TUBERCULOSIS.—At the meeting of the Berlin Medical Society, on February 25, after Professor Oscar Liebreich had presented his communication on his new remedy for tuberculosis, reports on cases treated by the method were submitted by Drs. PAUL HEYMANN and G. GUTTMANN, and PROFESSOR B. FRAENKEL (*Berlin Klin. Wochenschr.*, March 2, 1891). Dr. Paul Heymann has used cantharidinate of potash in 27 cases, in 10 of which the treatment had only just been begun at the date of the report. Of the remaining 17, 11 were suffering from tuberculous lesions of the larynx of a more or less serious nature. In all these cases the lungs were also affected, and in all except one there were bacilli in the sputum. They were all treated at the Poliklinik as out-patients, and made no change in their ordinary mode of life. The dose injected was from 1 to 4 decimilligrams; only once did the injection cause redness, but never supuration. The injections were, as a rule, given in the back, but in two cases the patients were so thin that the nates were chosen. Sometimes the injections were followed by headache and giddiness, and oc-

asionally there was slight diarrhoea, which ceased of itself. In some cases smarting in passing water was complained of, and one patient said he noticed blood in his urine after an injection of 4 decimilligrams. The following were the results of the treatment (which was in no instance supplemented by any other): After three or four injections the voice improved steadily, till hoarseness almost entirely disappeared. The patients felt much better. The bacilli, however, showed no change. In the chest the physical signs cleared up, and even disappeared in some cases; the expectoration became smaller in quantity, more mucus and less frequent; cough subsided, and in 4 cases ceased altogether; night sweats diminished, and in some cases disappeared. In one case hectic fever ceased after the fourth injection, but this result was unique. In tuberculous disease of the tongue the granulations became flatter and paler, and the ulcers became cleaner and began to heal, as is seen in syphilitic affections under the use of iodide of potassium. In one patient, who was almost voiceless and who was the subject of tuberculous ulceration of the larynx, after nine injections the ulcer had disappeared, and after three more the only abnormality in the larynx was a scarcely visible infiltration of the left vocal cord, whilst the physical signs in the chest had entirely cleared up. Another patient with catarrhal ulcers in the larynx was cured after ten injections; in three others suffering from similar conditions the infiltration and redness of the cords began to diminish as soon as the injections were commenced. Dr. G. Guttman related the case of a patient whom he had been treating for typical trachoma in the right, and recent granulation of the left, eye. The man developed laryngitis, and was treated by Liebreich's method. When Guttman saw him again there was no trace of inflammation in the left eye, while there was only a trifling swelling in the right. Professor Fraenkel said he had treated 15 patients suffering from laryngeal tuberculosis by the new method; 5 of these he presented to the Society. Under the treatment the redness and infiltration of the cords had steadily diminished, pain in swallowing had disappeared, cedema of the epiglottis and ary-epiglottic folds had subsided, while ulcers had gradually become smaller, and in some places had entirely healed. In one patient there was no longer any trace of ulceration.

In the cases in which the voice had been lost, it had been restored. In one patient Dr. Fraenkel had noticed the appearance of submiliary nodules which became yellow, broke down, and finally disappeared, leaving a scar in their place. In another patient there was at the date of the report a serious exudation at the level of the larynx, a fact which seemed to him to confirm Liebreich's explanation of the mode of action of

his remedy. When this patient coughed he brought up serous fluid from his larynx. The pain of the injection lasts some time, and in one case there was some difficulty in micturition after an injection of 1 decimilligram. Fraenkel thinks he has noticed a slight diminution in the number of bacilli, and the microbes seemed to have lost their reaction to coloring matters; they had to be kept in the staining solution for twenty four hours before they were sufficiently stained. The rapid improvement seen in patients submitted to the treatment was due to a direct action of the remedy on the bacilli. None of the cases could be said to be cured, but Fraenkel thinks that the most brilliant results may be hoped for from the method.—*British Medical Journal*.

SALOL IN THE TREATMENT OF DISEASES OF THE URINARY PASSAGES.—The drug has been recommended in the treatment of diseases of the urinary passages by Lejune, Neucki, Dreyfus and Sahli, in place of the balsams. DE SMET of the hospital St. Pierre of Brussels (*La Clinique*), has treated forty-seven patients with salol. Three of these patients presented arthritis with urethritis, the others were simple cases of urethritis, simple gonorrhœal cystitis with or without urethritis. A cure was noted in two of the cases with joint complications. Salol produced excellent effects but did not cause much change in the urethritis, when associated with injections it seemed to shorten the malady. It renders the urine antiseptic, as he was always able to find free salicylic acid in the urine. The patients ordinarily take the drug in quite large doses without any special derangement of the stomach or appetite. The dose should range from three to five grams daily.

Medicine.

SUSPENSION IN THE TREATMENT OF NERVOUS DISEASES.—RAULT (*Le Progrès Médical*, Feb. 28, 1891) contributes a critical review of the literature of this subject. He has constructed a table of reported cases, in which the results in 210 are given. Of these 162 were improved, and 48 unimproved. Notwithstanding the contradictory opinions that have been emitted by high authority the method seems destined to win a place in the accepted methods of treating certain nervous diseases. It is probable that further observations will limit its application to cases more likely to be benefited; its too indiscriminate use may bring a really good method into disfavor.

INJECTIONS OF DOG'S SERUM IN TUBERCULOSIS.—HÉRICOURT, LANGLOIS AND SAINT-HILAIRE (*Gazette Médicale de Paris*, Feb. 7 and 14, 1891) have presented to the Société de Biologie the results obtained by them with injections of dog's serum in the treatment of tuberculosis. The first case, by M. Héricourt, was one of well ad-

vanced pulmonary tuberculosis, with caseous pneumonia and cavities in both apices. On December 6th last the patient received one cubic centimetre of dog's serum which the writer calls "hémocyste," as being a short and convenient term. After receiving 19 cubic centimetres there was a marked improvement in the general and local conditions, the cough lessened, expectoration diminished, and a gain of eight pounds was noted in weight.

Langlois describes a case with cavities and abundant expectoration that was markedly improved by four injections extending over a period of ten days. The cough and bronchial secretion lessened and the patient gained two pounds in weight.

The case of Saint-Hilaire was one presenting marked pulmonary involvement with invasion of the larynx, night-sweats, hectic, etc. Seven injections were given extending over a period of nineteen days, the quantity of each injection varying from 1 to 3 ccm. There was appreciable increase in the patient's strength, the night sweats disappeared, the laryngeal symptoms improved, and there was a gain of six pounds in weight.

A second was in the early stage with rough crepitant râles at the apex, some consolidation with involvement of the larynx. After eight injections the physical signs disappeared and the laryngeal symptoms improved. In this last case the sputum was examined and found to contain abundant bacilli. The writer does not say whether they were looked for after the treatment began.

The injection of hémocyste does not cause any or but slight local reaction and no general disturbance of the system. The first case mentioned by Saint-Hilaire had proved refractory to other treatment, such as creosote, etc.

Surgery.

TEST OF COMPLETE CHLOROFORM NARCOSIS.—GUELLIOT (*Journal de Médecine de Paris*) claims that the absence of the cremasteric reflex, is one of the best and readiest means of determining complete chloroform narcosis. The quickness and force with which the reaction is produced is some index of the degree of narcosis. The point seems to be one well worthy of consideration by the practical surgeon.

Obstetrics and Diseases of Women.

PARTIAL INVERSION OF THE UTERUS FROM TRIFLING CAUSES.—DR. S. REMY (*Archives de Toccol. et de Gynéc.*, February, 1891), describes two cases of inversion, the one from slight force in extracting the placenta, the second from a more passive cause. A woman, aged 32, aborted early in her first pregnancy. Hypogastric pains followed, and she soon became pregnant again. Labor occurred at term; it was rather lingering, but was left to nature. Ten minutes after the

birth of a rather heavy female child, the midwife placed her hand on the fundus and pulled gently on the cord; the placenta came away. Then the midwife found that the uterus could no longer be felt above the pubes. A large tumor filled the vagina. Dr. Remy was summoned, and came a few minutes after the accident. The patient felt queer, but there was no shock and little hæmorrhage. He could feel a part of the uterus, deeply cupped, above the pubes. By steadying this part with one hand and pressing with the back of the fingers with the other on the vaginal tumor, he succeeded in reducing the inversion, which did not recur. Inertia or weakness of the muscular tissue at the placental site had caused failure of retraction when the placenta separated, and intra-abdominal pressure forced that part of the uterus downwards into the space left by the retracting placenta. In uterine inertia clots caused by hæmorrhage no doubt check the tendency to inversion in many cases. In the second case the patient was an anæmic young lady. Several floodings followed her first labor. At the end of a month, after free dosing with ergotine, very severe hæmorrhage took place. The abdomen was flat, the uterus could not be felt above the pubes. The os was patulous and blocked by a soft presenting body covered with fetid blood. Careful bimanual palpation proved that there was partial inversion with retained fragments of placenta. The inverted surface was dressed with antiseptics. Two plugs of wool, covered with iodoform gauze, were placed against it to control the hæmorrhage. This dressing was renewed daily. Two days later two pieces of placental tissue came away. No more bleeding occurred. On the seventh day the patient was much better, the cervix was closed, the inversion had reduced itself. Fourteen months later the patient was in stronger health than she had ever enjoyed before in her life. Leucorrhœa, constant down to the end of the pregnancy, had ceased altogether. The period was regular but very scanty. The retained placental fragments had caused great congestion of the region of the uterus to which they were attached. Hence there was softening of that part of the uterine wall, the contractions causing it to be gradually drawn downwards. Such is Dr. Remy's explanation.—*British Medical Journal*.

Hygiene.

DISINFECTING POWER OF SULPHUR FUMIGATIONS.—One of our prominent surgeons once told the writer that the only value of sulphur fumigations was to destroy such unfortunate representatives of *cimex lectularius* as came within range of its influence. Notwithstanding this pessimistic view, many physicians rely upon sulphur fumigations, and in many of our hospitals it still forms one of the appropriate ceremonials at the altar of antiseptics. Undoubtedly much of the

disfavor that has met this method of late years has been caused by experimental work, in which the bacillus anthrax has been the test organism employed. The researches of THOINOT (*Annales de l'Institut Pasteur*) show that while the spore forming bacilli, anthrax, malignant œdema, etc., resist the bacilli of tuberculosis, glanders, typhoid, cholera, and diphtheria are destroyed by the action of the sulphur. The writer thinks that absolute security is assured if 60 grams are burned to each cubic meter of space with the room carefully sealed.

Bacteriology.

KOCH'S TREATMENT: EXPERIMENTS ON CATTLE.—The experiments recorded in the *British Medical Journal* of January 24th afford subject matter for very careful consideration. In three cows in which tuberculosis was undoubtedly present, as determined by physical examination and by the presence of bacilli in the bronchial mucus and in the milk and by the changes in the lymphatic glands, "reaction" was obtained in proportion to the amount of fluid injected, whilst in healthy control animals no rise of temperature was noticed. It is evident from this that whatever may be the ultimate result of treatment by Koch's fluid we have in it an agent that may prove of the greatest value in helping to form a diagnosis of tuberculous disease in cattle, and we have here an indication of the lines on which, for a time at any rate, much of the experimentation with Koch's lymph must be carried on. Some physicians and surgeons have been so unfortunate in the selection of their cases that they have already resolved that until more is known of the action of the remedy on the human subject they will be very chary indeed of using it as a therapeutic agent. The veterinary surgeons, however, will scarcely be deterred by such considerations. It is often an exceedingly difficult matter to determine whether a cow is tuberculous or not, and if these experiments are to be relied on, all that is necessary to obtain confirmation of the diagnosis is to inject some of the fluid. We can scarcely look forward to this being used as a method of treatment for the disease in cattle (except in the case of pedigree animals), but in the hands of veterinary surgeons it will prove an instrument of precision of the very highest value. It will enable them to state in all doubtful cases what animals should be condemned as tuberculous and which should be allowed to remain in the cow-house without danger of infection to the other cattle. These experiments certainly open up a most important and fruitful branch of research to the veterinary profession. And it will at once suggest itself that the consideration of this question might with advantage occupy the attention of the Royal Commission on Tuberculosis now sitting.

P. O. HOOPER,

JNO. B. HAMILTON, Prest. of the Board,
Secretary.

THE TURKISH BATH AS A REMEDY.

For over a thousand years the hot air, or Turkish bath, has been used both as a luxury and therapeutic measure. Thirty years ago MR. URQUHART, DR. ERASMUS WILSON, of London, and others, described and urged the bath as a remedy for many diseases; and since that time it has been slowly coming into practical use, and is now recognized as a remedy of positive value.

While it has been very largely in the hands of irregulars, who have claimed the most extravagant therapeutic powers, whenever it has been used in scientific medicine it has been retained and adopted as invaluable. In Europe many government asylums and hospitals have the most elaborate baths, and sanitariums and private hospitals for chronic diseases depend on the bath as a remedy. In this country much indifference prevails. Except in a few sanitariums and public baths in the large cities, it is almost unknown; yet writers and men of practical experience are always warm defenders of its powers and virtues.

The number of persons who use the bath as a preventive of disease among the laity are increasing constantly. The scientific reason is no doubt to be found in the fact that copious perspiration in the high, dry temperature of the hot room is a powerful eliminator of effete and poisonous matters from the system. The excessive stimulation of the cutaneous circulation is also of great value in relieving obstructions and congestions in both the glandular and circulatory systems. The marked change and relief which follows the use of this form of bath is due to the profound diversion and equalization of the fluids of the body.

The massage which follows the excessive forced perspiration is a muscular tonic of equal value. Experience proves most conclusively that free, artificially produced perspiration is not followed by exhaustion, and also that the three stages of the bath—the sweating, shampooing and the final cooling, are all true physiological processes. Thus the combined impetus of the shampooing and the heat stimulates powerfully the nervous, vascular and absorbent systems. To supply the waste of fluids eliminated by the skin, the cutaneous system of blood-vessels draw upon the internal trunks, thoracic, abdominal and cerebral. The exalted condition of the circulating, nervous and glandular systems, induced by friction, augments the vital force, restores the balance in obstructive disorders, and promotes secretion and absorption. With each muscle, nerve and blood-vessel, thus stimulated, the results are greater tone and vigor.

The class of cases from which the most benefit will be obtained by the baths are the rheumatics, the neuralgics, and those suffering from malaria, blood-poisoning and general plethora. Another large class who are frequently under the physician's care, are those who are over-fed, and who do not exercise properly, or are underworked.

Often they are brain and office workers who do not go out in the open air much, and rarely have any muscular exercise, but eat heartily. Another class of cases become exhausted and suffer from mental anxiety, overstraining the nervous system; continuous care, worry and excitement bringing on all forms of functional nerve disturbances.

All these cases are chiefly prominent in defective secretions and irregularities of the bowels

and skin. Digestive disturbances and temporary congestions of all sorts come and go. The heart is irregular in its action; murmurs and sounds are heard, which, although formidable at the time, disappear in a few days. Both albumen and sugar appear in the urine, and disappear in a few days. Often these cases furnish symptoms at different times of very serious diseases, and the recent graduate, or the unthinking specialists, are surprised to find their most positive diagnosis fail, while some elderly practitioner, supposed to be far behind the front line of exact science, will step in with a strong cathartic, and, perhaps, an old fashioned hemlock sweat, and all the grave symptoms pass away. These cases go from one physician to another, and are the object of much anxiety and professional unpleasantness both in and out of the regular profession. They are supposed to be incurable and finally go to a sanitarium where the Turkish bath is the chief remedy, or to some city public bath, and rapidly recover; frequently giving credit for the cure to some proprietary medicine, which was accidentally used at the last moment. If the family physician had understood the value of the bath, and prescribed it, his reputation would have been unimpaired.

Where the baths are not accessible away from large cities, sanitariums must supply the want. Country and village physicians who have large houses could, at a trifling expense, have a bath, which would not only bring substantial returns financially, but would increase their power, and enable them to cure many cases now thought incurable. There can be no doubt that the Turkish bath will be largely used in every town and village of the country by physicians in the near future. Simply because it is a great natural means of restoration, and along the line of physiological processes.

The Turkish bath belongs to rational therapeutics and should be rescued from the realm of quackery and studied and used on scientific principles. It is also evident that hot air, high heat, water and massage are most powerful agents in disease, and should not be confined to hospitals and large establishments, but should be made available for every physician, in some form or other. In Europe the Turkish bath is attracting increased attention, and a number of excellent papers on the value of the baths in certain diseases have appeared.

Practically the Turkish bath has been used in principle, in the various sweats common in domestic medicine. If to this had been added expert rubbing and shampooing, and careful after treatment, the result would have made this means very prominent as a method of treatment.

The public seem to more fully appreciate the use of the bath than medical men, and this is a most serious mistake. They should be the advisers and authority on this remedy. They should know what class of cases would receive the most benefit from these baths, and advise them. The baths in large cities should be under the care of scientific men, who would give a thorough study of the cases and the effects of the baths. In smaller towns the family physician could do this. If this was done the present confusion of theory and experience would give way to established facts, and the Turkish bath as a remedy would take its place among the great therapeutic agents, of priceless value in the prevention and cure of disease.

THE INCREASE OF OUR MEMBERSHIP.

The permanent enlargement of our Association must depend upon the value of the returns which it will be able to make to its individual members. It must be made able to so compensate men, that once they become members they will remain such, else, when convenient, they will maintain their membership, but when at all inconvenient they will forfeit it. This has been the history of the Association for the last forty years. It is at this point, it is to be hoped, that THE JOURNAL is coming to our help, and will hold many to a permanency which might not be otherwise secured. When it comes to be an everywhere acknowledged fact that THE JOURNAL is worth, to the masses of the profession, much more than its cost, there will be a two-fold reason for one's maintaining his membership. Just in proportion as men come to appreciate the advantages to be derived from attendance at its annual meetings, and to value its accredited organ as a medical journal, to that extent may we look for permanency in the membership of the Association. That THE JOURNAL is thus asserting for itself a place is evident from the fact, that nearly one thousand men are receiving it upon subscription, although they have no relation whatever with the Associa-

tion. There is no reason why its value may not be more and more developed until THE JOURNAL shall become the great centralizing and unifying power in our medical profession.

The permanent attractive influence, which more than all others shall draw men year by year to our annual meetings, must centre in our Sections. We shall stand or fall, as these shall or shall not give to the profession such returns as shall well repay, for the labor and expense incident to attendance at the annual meetings. It is absolutely essential to our permanent growth that the Sections be made as nearly perfect as possible in their organization, and that they command the best of talent, not only to interest those present but, through the medium of THE JOURNAL, to profit the thousands who must necessarily be absent. Give to the medical profession of America value received and they will come to be enrolled in the membership just as fast as they come to know the worth of the Association to medical men.

The next question to be considered is that of more fully acquainting physicians with the Association and bringing them into such relation, that they shall rightly appreciate its value. It need not be a matter of material expense, according to the present rule, for any regular physician to become a member of the American Medical Association *by application*. It is a first essential that he be an accredited member of some local medical organization which is in affiliation with the Association. It is competent for the president and secretary of that local society to so certify, and with their certificate of his standing he has simply to inclose with his application for membership a fee of five dollars, and he will be duly enrolled and will receive THE JOURNAL without additional expense, so long as he shall continue in good standing with his local society and shall pay his annual dues. Thus it is possible for physicians all over this broad land to become members by application, and to receive THE JOURNAL regularly, upon the payment of this small fee, without ever incurring the expense, unless they shall so choose, of an attendance upon an annual meeting; and yet we are confident that the influence of THE JOURNAL will bring the great majority of these into active membership as time goes on.

Again, we trust the time is not far distant when in some desirable way there may be such a union of the State Societies with the Association that

each member of a State Society, by reason of that relation, will also be a member of our National Organization. We believe this to be feasible; we believe it to be eminently desirable. We hope, therefore, that the resolution offered at the last session by DR. CULBERTSON, of Cincinnati, and which will be called from the table at the coming meeting, will receive, on the part of our members, the serious consideration which we believe the subject deserves, and that it will be referred to an able committee who shall give it full consideration, the results to be embodied and submitted, in the form of a report, to the Association at a subsequent session.

Is it too much to anticipate the time when this National Association shall represent the entire membership of all our State organizations? We are building for the future needs of a mighty Empire. Let us build largely, wisely and well.

It is surely safe for the Association to refer this subject and that of the development of the Sections, to which we alluded last week, to an able and representative committee, who shall consider most carefully the subjects so referred, and with instructions to submit such report at the next annual meeting.

QUESTIONS OF IMPORTANCE TO THE MEMBERS ANSWERED.

We have received the following letter from DR. FRED. J. PARKHURST, of Danvers, Ill.:

To the Editor:—There is a great amount of ignorance prevailing in our section of the country in regard to the present Editorial management of THE JOURNAL. This will be a subject of great importance to the members of the Association when they come to prepare their ballots on the question of moving THE JOURNAL to Washington. By answering the following questions I am sure you will confer a favor on a large number of the members of the Association who are at present ignorant of the facts.

1. Who is the present Editor of THE JOURNAL and how long has he occupied the position?

2. Has Dr. N. S. Davis at present any official connection, either editorial or otherwise, with the management of THE JOURNAL?

3. What is the date of Dr. Davis' resignation as Editor-in-Chief of THE JOURNAL?

4. Was Dr. John B. Hamilton Editor of THE JOURNAL at one time? If so, for how long?

FRED. J. PARKHURST, M.D.

Dr. N. S. Davis was Editor-in-Chief of THE JOURNAL until Jan. 1, 1889. Dr. John B. Hamilton, Surgeon-General of the Marine-Hospital

Service, was Editor-in-Chief, from January 1, to February 1, 1889. Dr. N. S. Davis, at the request of the Board of Trustees conducted *THE JOURNAL* from February 1, 1889, to May 1, 1889. The Secretary of the Board of Trustees, Dr. John H. Hollister, was then made Supervising Editor, and has acted in that capacity up to the present date.

EDITORIAL NOTES.

TREATMENT OF TUBERCULOSIS WITH VACCINE LYMPH.—As a further indication of the stimulus given to the experimental medical work by Koch it may be mentioned that a New York physician, Dr. J. Hilgard Tyndale, has announced, before the New York County Medical Association, March 16, 1891, the results obtained upon twenty-three patients from the hypodermic use of bovine vaccine lymph. Dr. Tyndale divides his tuberculous cases into four classes, viz.: 1. Those in whom the general condition is good, the local lesion limited and just beginning to be active. 2. Those in whom the general condition is below par and the local lesion not great. 3. Those in whom constitutional impairment is grave and the local destruction advanced and disposed to be active. 4. Those in whom the local lesion is extensive but not active, and the general condition reasonably good.

The writer believed that investigators were on the right track in seeking to overcome this disease by hypodermic inoculations of animal virus or chemical substances of marked toxic effect. In using the vaccine lymph he had made one injection every six or seven days. There was no active reaction. Benefit had shown upon all the symptoms, both subjective and objective.

Other measures of relief, such as tonics, lung gymnastics, etc., were not discarded, but were withheld until benefit from the lymph was well established.

The author believed that more than one animal lymph, or chemical intoxicant, would be found to have an abortive influence upon the tuberculous process, and that his experiments thus far with vaccine lymph demonstrated the correctness of the assertion. Nine of the patients upon whom this method of treatment had been tried, were presented before the meeting.

In this connection we are led to say that scarcely a day passes without new knowledge

coming to us of patient and conscientious research along this new path, and the world at large is waiting to place the very highest honors upon those results which break the force and destroy the power, not alone of this mighty disease—tuberculosis, but those of like nature as well. No one can fight, in this manner, with success, against disease as a unit, but in specific directions, and with that stern singleness of purpose which so marks our discoverers, the possibilities of future medicine are scarcely to be measured.

INFLUENZA IN NEW YORK CITY.—The medical press now chronicles the occurrence of influenza in the metropolis, though in not as severe or general a form as maintained a year ago. Chicago's Health Commissioner is quoted as claiming that it is not so much the influenza which that city has of late been afflicted with, as a lack of the disease-opposing virtue of bright, clear sunshine. The month of March was particularly gloomy and cloudy, and the uncleaned atmosphere therefrom tended to rapidly precipitate untoward conditions in existing diseases of the respiratory system, as well as to predispose the onset of such affections.

APPENDICITIS.—This subject is still a favorite one among surgeons, really occupying quite the first position in the great field of surgical discussion. The appendix is but a small portion of the human anatomy, and yet it appears that it has a wonderful significance which in the past did not receive that degree of attention it, in the light of our present knowledge, merited. In a very short time a great advance has been made by surgeons along this line. In the last number of the *Annals of Surgery* almost sixty pages are devoted to this subject of appendicitis, consisting of five papers by as many authorities in this branch.

PARKIN PRIZE, ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.—The late Dr. John Parkin, Fellow of the Royal College of Physicians, Edinburgh, left a bequest of one hundred pounds sterling for the best essay, "On the Curative Effects of Carbonic Acid Gas or other forms of Carbon in Cholera, the different Forms of Fever, and other Diseases." The prize is open to competitors of all nations. Essays intended for competition must be written in the English language, and must be received by the Secretary, Dr. G. A.

Gibson, not later than December 31st, 1892. Each essay must bear a motto, and be accompanied by a sealed envelope bearing the same motto outside and the author's name inside. The successful candidate must publish his essay at his own expense, and present a printed copy of it to the College within three months after the adjudication of the prize.

NEW YORK ACADEMY OF MEDICINE.—The property of this great and representative medical body is now valued at \$400,000, with a debt of only \$30,000.

COLORADO FOR CONSUMPTIVES.—Notwithstanding the possibilities which have been looked for, and hoped for, from tuberculin, there continues even an increased interest in the beneficial influences of the Colorado climate. Much information is advanced to show that factors undeniably dwell in that region which exert a wholesome, and many times curative, effect upon wasting diseases, notably phthisis.

THE OPHTHALMOSCOPE IN NERVOUS DISEASES.—Dr. G. Sterling Ryerson, Professor of Ophthalmology in Trinity Medical College, Canada, arrives at the following conclusions under the above heading: 1. That diseases of the brain and spinal cord are frequently associated with ocular disturbances. 2. That serious eye trouble may be present without subjective symptoms. 3. That eye troubles often precede and give warning of impending nerve disease. 4. That disease of the optic nerve and retina are of great diagnostic value in nervous diseases. 5. That it is the duty of the physician to examine the eye and its muscles in all cases of nervous diseases.

THE RESULT OF MEDICAL LEGISLATION IN NEW YORK.—In the State of New York there is now a compulsory three years course of study, prefaced by a compulsory preliminary examination, and ending by an independent examination for a license to practice before a Board of Medical Examiners appointed by the State.

A FULL MEETING ANTICIPATED.—By reason of its location the next meeting will be largely attended by gentlemen resident in the East. By no means let the West, the South-west, or the South, fail of their full quota of delegates and members. We anticipate that the coming meeting will be the largest one in the history of the

Association. Questions of unusual interest are to be considered and it is important that every portion of the country should be fully represented. What we say to one we say to all, God!

SMALL-POX IN ST. LOUIS.—A slight epidemic of this disease is reported to have been in progress in St. Louis during last month. Every precaution was taken, however, and a prompt limitation was enforced. As so often occurs, the exact origin cannot be clearly ascertained.

CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS.—The meetings of the Congress of American Physicians and Surgeons will be held in Washington from 3 to 6 P.M., September 22d to 25th, 1891. William Pepper, of Philadelphia, is Chairman of the Executive Committee.

THE NATIONAL ASSOCIATION OF RAILWAY SURGEONS.—The Annual Meeting of this Association will convene at Buffalo, April 30, and be in session for four days. This important organization is assuming immense proportions, and the meeting at Buffalo bids fair to be one of exceptional interest. The date of the meeting is so arranged that large numbers of its members are preparing to go from there to the meeting of the American Medical Association at Washington. Why not go bodily, and give the Association such an accession as it never received before. First to Buffalo, gentlemen; then on to Washington.

THE TENTH CONGRESS FOR INTERNAL MEDICINE was held in Wiesbaden from April 6 to 9. Among the more important subjects discussed was Koch's method of treating tuberculosis of the lungs and other internal organs.

DR EUGEN JENDRASSIK, professor of physiology in the University of Buda-pest, is dead. He was widely known as a contributor of scientific monographs. He invented a myograph of practical utility and also describes a method of reinforcing the reflexes of the lower limbs, that is generally known by his name.

MEDICAL ITEMS.

A PARISIAN MEDICAL LIBRARY.—The library of the Paris Ecole de Médecine, which contains some 40,000 volumes, will shortly be transferred to its new quarters overlooking the Boulevard Saint Germain. The new building contains a large room with places for 150 readers, and other

smaller rooms where anatomical models, etc., will be open for the use of students. A special section will be reserved for a collection of autographs of the Deans of the Faculty from 1324 to 1789.

A LARGE BRAIN.—Wilson (*Edin. Med. Jour.*, January, 1891) reports the removal of a brain which weighed 64 ozs., in the post-mortem room of the Royal Edinburgh Asylum, from a man 75 years of age, 5 feet 10 inches in height. The circumference of the head was 24 inches. The brain was very anæmic, contained hardly any fluid, and was put on the scales immediately after removal. It was described as "large vertically, well-shaped all over, with convolutions if anything larger than normal, and sulci wide over the vertex, except the occipital."

The man's intelligence seemed to have been above the level required for his work as a sawyer, but was never of a high grade.—*N. Y. Medical Journal*.

THE NEW POLYCLINIC.—The handsome new building of the Philadelphia Polyclinic, on Lombard Street, west of Eighteenth, was formally opened April 2 by Lieutenant-Governor Watres as a charitable institution of the State. In making the formal transfer of the building to the trustees, Dr. Thomas S. K. Morton, chairman of the Building Committee, said: "The importance of this occasion to the city and State cannot be overestimated, for it is the establishment of a unique medical school, and all the undergraduate medical colleges send their representatives with greetings to the successful launching of this institution."

DR. SIEBERT has resigned the editorship of the *New Yorker Deutschen Medicinischen Monatsschrift*, and Dr. Heppenheimer has been appointed to fill the vacancy.

THE FATTEST MAN IN THE WORLD is said, by the *St. Petersburg Med. Wochenschr.*, to live in Danville, U. S. A. His name is Mr. John Hansen Craig, is 35 years of age, and weighs 907 American or 925 Russian pounds.

HERNIA AMONG RUSSIAN ARMY RECRUITS.—It is stated that in Russia among the Jewish youth, who are subject to conscription for military duty, they have a secret plan for the self-production of inguinal hernia, in order to bring about rejection by the medical examiners. An instrument re-

sembling the ordinary glove-stretcher is used as a means for the gradual dilatation of the inguinal canal.

ANALYSIS OF "ANTIKAMNIA."—Professor C. M. Ford, of Denver, has reported that the above is a mechanical mixture of acetanilid 85 parts and carbonate of soda 15 parts. The presence of the latter will explain the effervescence complained of by several pharmacists when acid preparations, such as wine of pepsin, have been added to the antikamnina.

Two Chinese physicians, Drs. Chon-yuan-yeh and Cheng-bhi piao, have been sent by their Government to Berlin, for the purpose of studying the results obtained in the use of Koch's lymph.

PHOTOGRAPHING IN COLORS.—The recent announcement, which is producing such interest in the general scientific field, may well receive the attention of the great medical body. The value of this discovery will be felt, in no small degree, by those engaged in medical research; and to the surgeon, pathologist, microscopist, physiologist, *et al.*, the force of demonstrations will be increased by the application of this means.

MEDICAL AND SURGICAL COLLEGE OF NEW JERSEY.—The above was the title assumed by a so called institution of medical learning which had its local habitation on Montgomery street, in Jersey City. The last edition of "Polk's Medical Directory" contains a card setting forth some of its claims and a list of its faculty in 1890. The said college no longer exists. The New Jersey State Board of Medical Examiners has caused the introduction of a bill repealing the charter of the school before the legislature now in session, and the bill has been passed and signed by the Governor. Dr. W. P. Watson, Secretary of the State Board, has been influential in bringing about the desired result, and he with other members of that Board are to be congratulated upon their success in ridding their State of a concern having strong points of resemblance to one of the old-time Buchanan diploma mills.

A PROPER RECOGNITION.—Dr. Edith Pechy-Phipson, appointed a member of the senate of Bombay university for her public spirit in speaking against child marriage in India, was one of the first women to take the medical course of Edinburgh university, which she entered in 1869.

TOPICS OF THE WEEK.

HYPNOTISM

An interesting article appears in the *British Medical Journal* of March 28, from the pen of Mr. Ernest Hart. He sums up in the following words his general conclusions: To sum up then in a few words the actual state of the question, an impartial observer might, in my opinion, conclude that hypnotism is a pathological modification of the nervous system, which always indicates that the subject belongs to a neuropathic class. The complete and typical form of hypnotism described by Charcot is rare. Suggestion plays a considerable part in hypnotic phenomena, but there are somatic phenomena which are independent of it. Hypnotism may frequently be dangerous, and very rarely useful. It may be the cause of crime, or of mental disorder; it can really cure no disease not more easily curable by simpler and less dangerous methods. A considerable number of facts attributed to it which have most impressed the public imagination, such as the actions of medicines at a distance, the so-called telepathic communications or communications made without speech, and the *clairvoyant* phenomena sometimes described, are mere errors of experiment arising from insufficient precautions and a too vivid imagination. Precisely those phenomena which have been most publicly talked about and excited most interest in "psychical circles" so-called, are the least real. The hopes which the therapeutic hypnotist aroused have not been realized, and any expectations of producing by hypnotic methods any desirable moral or mental effect rest upon a totally inadequate basis of fact, and are far from being promising.

BACTERIA PROTEINS AND THEIR RELATION TO INFLAMMATION AND PUS FORMATION.

Dr. H. Buchner gave last year three lectures on the relation of bacteria proteins to the inflammatory and pyogenic process, in which he said that it is generally supposed the proximate chemical cause of inflammation and formation of pus is the presence of decomposing substances, the chemical produce of bacterial cells; but that ptomaines and toxins, and even toxalbumens, are preeminently nerve poisons, and in only a few of them, as in cadaverin and putrescin, can a pyogenic effect be traced as well. These substances do not, therefore, explain the inflammatory and pyrexial character of most infectious processes, including suppuration, especially as Lange and Roemer have proved by their experiments that no decomposing substances have any considerable affinity for leucocytes. Substances having such affinity, however, do exist, according to the author, and he has already referred to them in a previous publication. They are parts of the bacillary body, that is, of its plasma—namely, the so-called bacteria proteins, which Niencki had already studied in 1880 without imagining their great pathological importance. Dr. Buchner has shown by his experiments that bacteria proteins have the strongest affinity for leucocytes, and that in man they also have an intensely inflammatory effect. A hypodermic injection

of a few milligrams of the protein of bacillus pyocyaneus caused an inflammation which, though non-infectious and free from bacilli, and almost deserving the name of chemical inflammation, presented all the clinical symptoms of erysipelas with lymphangitis; the course of this inflammation is, however, more rapid and more benign, and the general state of health is little disturbed. The author considers that the proteins can exercise their activity only when they have been secreted from the bacterial cell, and that this secretion takes place exclusively when the cell is in "involution"—that is, dying, or at any rate morbidly affected. This also explains why in anthrax of rodents, when virulent bacilli are indefinitely increased in the blood and never die, there is no sign of inflammatory leucocytosis, while a hypodermic injection of very weak or even completely sterilized anthrax culture has a strong pyogenic effect in the same rodents. Of seven different bacilli which the author has been able to experiment upon the proteins of the typhus bacillus seem particularly effective. It is very easy to obtain the protein of Friedländer's pneumonia bacillus, and still more so that of the bacillus pyocyaneus. The protein has the same chemical reaction as all albuminoids, and most nearly approaches in that respect vegetable caseins. The author subsequently experimented on vegetable caseins, especially on the gluten casein of wheat, and the result was remarkably similar to that of experiments with bacilli.—*Lancet*.

DOCTORS AND POLITICS

It is not generally known, says the *San Francisco Chronicle*, that Marat, the Revolutionist dispatched by Charlotte Corday, was a physician, and that he had a certain success in treating consumption. It is recorded of him that he cured a titled lady of this disease in its advanced stages, and that her gratitude to him knew no bounds. Unfortunately he was enticed into politics and prevented from pursuing his studies further in a direction that might have made his memory revered instead of detested.

For some reason doctors seem to drift naturally toward politics and radicalism, perhaps because their profession tends to render them skeptical. In Brazil and the Argentine Republic they have shown themselves decidedly ambitious. The celebrated Dr. Charcot is a radical whose principles verge on the revolutionary. Clemenceau gave up his medical practice years ago to devote himself to politics, and though he is a man of great talent and a brilliant orator, his political efforts have not contributed to his personal advancement or been of great benefit to his country. Besides Clemenceau there are from forty to fifty physicians in the French Chamber of Deputies.

ASSOCIATION OF AMERICAN PHYSICIANS IN BERLIN

There has been formed in Berlin an association under the above title. Dr. Judson Dolland, of Philadelphia, was elected President; Dr. F. Weber, of Milwaukee, Secretary; Prof. Miller, of Philadelphia. Dr. Amos, of Iowa, Dr. H. Douglas, of New York, together with the President and Secretary, were elected as a Committee on

Constitution. Dr. H. R. Brooks, of New York City, Dr. Louis Frank, of Louisville, Dr. Crystal, of Baltimore, Dr. Neal Mitchell, of Florida, Dr. Marple, of New York, and Dr. Kennedy, of Montreal, were appointed a Committee on Information to New-Comers and on Organization of Special Private Courses.

The principal objects of this association are: 1. The arrangement of medical work and the formation of special private courses, so that any desired instruction may henceforth be obtainable at this University. 2. The giving of advice to new-comers regarding instruction, lodging, books, instruments, etc. 3. The reading and discussion of papers of general interest, exhibition of patients and demonstration of specimens in all lines of work taken up by members. 4. The furthering of mutual ends by a more extended acquaintance of the physicians here.

We doubt not that this organization of American physicians sojourning for a period in Berlin will be found to be helpful as well as pleasant.

THE NEW PATHOLOGICAL DRAMA.

The modern novel has accustomed us to the interweaving of physiology and pathology with romance. The introduction of these sciences into the drama is quite a new and wholly unwelcome departure. A week or two ago, at the Royalty Theatre, the elect who hail Heinrich Ibsen, the Norwegian dramatist, as the new Shakspeare, contrived, by means of a "subscription representation," to elude the authority of the Lord Chamberlain, and produced to a crowded house Ibsen's much talked-of play, *Ghosts*. The theme is heredity. After an instructive discussion between his mother and a clergyman on free sexual relations, Oswald Alving, the hero, is overheard in an adjoining room making advances to her pretty servant in a manner more suggestive than decorous. The maid in question turns out to be his own half-sister, and Oswald at once proceeds to discuss the rectitude of that relationship countenanced by the Pharaohs, but is happily cut short by brain disease, the result of inherited syphilis, in a manner which may be deemed natural by the playwright, but which is wholly unknown to the physician. The question of the desirability of shortening his days by poison is under consideration when the curtain falls. To take all the disintegrating views of viewy people, to make them become self-conscious in plain John and Betsey, and operative on their lives, to adorn this "psychological study" with a quasi-scientific exactitude, as absurd and untrue as it is pretentious, is the rôle of the new great realist. There is some stagecraft, but the dramatic pamphleteer is much more apparent than the artist. It is sadly to be feared that the sanity of true genius has not appeared in this latest fad of staging grotesque pathology and ethical Nihilism. To the strict scientist such a play is an amusing travesty; to the moralist it is portentously significant. From the purely literary point of view, it would be well if admirers of novel genius should adopt Matthew Arnold's advice, and carry about with them a gem or two of the true masters to serve as touchstones in distinguishing the spurious and ephemeral from the enduring and truly great.—*British Medical Journal*.

PATHOLOGY OF GRIEF.

That severe mental distress or fright sometimes produces physical disease, and occasionally even death, is an admitted fact, although the way in which it acts has hitherto been but little studied. In order in some measure to supply the deficiency in our knowledge regarding this matter, Dr. G. Bassi has recently made a number of observations on animals which apparently died in consequence of capture. Birds, moles, and a dog which had succumbed to conditions believed by Dr. Bassi to resemble those known amongst human beings as acute nostalgia and "a broken heart" were examined post-mortem. Generally there was hyperæmia, sometimes associated with capillary hæmorrhages of the abdominal organs, more especially of the liver, also fatty and granular degeneration of their elements, and sometimes bile was found in the stomach with or without a catarrhal condition. The clinical symptoms were at first those of excitement, especially in the birds, these being followed by depression and persistent anorexia. The theory suggested by Dr. Bassi is that the nervous disturbance interferes with the due nutrition of the tissues in such a way as to give rise to the formation of toxic substances—probably ptomaines—which then set up acute degeneration of the parenchymatous elements similar to that which occurs in consequence of the action of certain poisonous substances such as phosphorus, or to that met with in some infectious diseases. In support of this view, he points out that Schule has found parenchymatous degeneration in persons dead from acute delirium, and that Zenker found hæmorrhages in the pancreas in persons who had died suddenly; he refers also to some well-known facts concerning negroes in a state of slavery and to the occasional occurrence of jaundice after fright. He hopes that these hints may induce medical officers of prisons and others to study both clinically and anatomically this by no means uninteresting or unimportant subject.—*The Lancet*.

BIOLOGICAL ACTION OF IRON AND MANGANESE.

Dr. Fausto Faggioli has published in a recent issue of *La Riforma Medica*, some notes of a research upon the physiological behavior of iron which he has carried out, with Professor Pellacani's assistance, in the Bologna laboratory of Forensic Medicine. From these it would appear that iron enjoys the property of setting up mitosis or nuclear change and cellular increase, especially in cultures of unicellular organisms such as protozoa. Under some circumstances manganese will act in the same way, but Dr. Faggioli was unable to find that any other metal could do so.

AMERICAN DENTAL ASSOCIATION.

The executive committee have decided on Saratoga Springs as the next place of meeting of the American Dental Association, commencing first Tuesday in August, 1891. It is hoped by the committee that each society will send delegates, that there may be a full representation from all parts of the country. J. N. CROUSE, 2231 Prairie Ave., Chicago, Ill., is Chairman of the Executive Committee.

PRACTICAL NOTES

PRESCRIPTION OF CHLORALAMID.

Galiana recommends the following prescription when using chloralamid :

- R. Chloralamid, 45 grains.
Dilute hydrochloric acid, 5 drops.
Distilled water, 2 ounces.
Syrup of raspberry, 2½ drachms.

One-half of this amount may be given. This may be divided into four doses, one of which may be given every four hours. For rectal injection he recommends :

- R. Chloralamid, 50 grains.
Dilute hydrochloric acid, 3 drops.
Distilled water, 3 ounces.

Or the chloralamid may be dissolved in an infusion of tea to which should be added a considerable quantity of sugar.—*Medical News*.

PILOCARPINE IN GLAUCOMA.

Drs. Saint-Germain and Valude (*L'Union Med.*) recommend the following :

- R. Pilocarpine, 4½ grs.
Aq. destil., 2½ drs.
℞ ft. collyrium.

This collyrium is employed alone, or in alternation with a solution of eserine, in glaucomatous conditions of children, when eserine does not agree with the patient.—*The Prescription*.

PRURITUS HIEMALIS.

Corlett recommends the following topical applications in "winter itch" :

- R. Resorcin, 5j.
Glycerin, 5ij.
Aqua, ad. 5iv. ℞.

Sig. Apply.

- R. Menthol, 5ijss.
Glycerin, 5ij.
Aqua, ad. 5iv. ℞.

Sig. Apply.

- R. Ichthyol. ammon. sulph., 5j. to ijj
Glycerin, 5ij.
Alcohol, aa q. s. ad. 5iv.
Aqua, aa q. s. ad. 5iv. ℞.

Sig. Apply.

—*Boston Med. Journal*.

SALICYLATE OF SODA AS A CHOLAGOGUE.

Prof. Germain Sée in an article on hepatic colic, published in the *London Lancet*, calls special attention to the use of salicylate of soda, which he has found to be the most efficient of all cholagogues in promoting the expulsion of gall-stones. The well-known cholagogues were found worthless in this ailment, for they stimulate the biliary secretion by increasing the solid elements, which is not desirable.

Salicylate of soda stimulates the biliary secre-

tion by increasing its fluid element, which is the principal indication in the expulsion of gall-stones.

The cholagogue property of salicylate of soda was made known by Rutherford, but has not received much attention; with the additional recommendation of Prof. Sée, supported by his vast clinical experience, the remedy should be considered worthy of trial.—*Nova Remedies*.

SALICYLATE OF MERCURY.

For hypodermic injections Vacher uses the following solution :

- R. Hydrarg. chloridi corrosiv., 1 part.
Sodii salicylic., 2 parts.
Aque destil., 100 parts. ℞.

In this solution each cubic centimeter contains one centigram of salicylate of mercury. For use by the mouth a 1-1000 to 1-5000 solution should be used.—*Deutsche Med. Woch.*

TREATMENT OF TINEA TONSURANS.

Simpson (*Med. Analectic*) has had excellent success with the following treatment for ring-worm of the scalp and body : Cut the hair short and wash the scalp well with tincture of green soap, and apply the following solution with a camel's hair brush :

- R. Hydrargyri chlorid. corrosiv., gr. j.
Collodii, 5j. ℞.

This treatment may be recommended for three reasons :

1. The corrosive sublimate destroys the fungi.
2. The ether of the collodion penetrates to the root of the hair, conveying the corrosive sublimate to the seat of the disease.
3. The film formed by the collodion shuts off the supply of oxygen to the fungi and thus helps to destroy them.—*Pittsburgh Medical Review*.

RINGWORM.

Ringworm of the body is generally very amenable to treatment, judging from the numerous domestic remedies which act so successfully. Sometimes, however, an obstinate case is encountered and recourse is had to the physician. In such cases a rapid cure is desirable, and the application of the following, once daily, for two or three consecutive days, will generally prove successful :

- R. Hydrarg. bichloridi, gr. ʒ.
Tinct. benzoin co., 5j. ℞.
Paint over affected parts.

Care should be exercised not to paint too large a surface, as the above mixture is toxic. If an excoriation exists it should not be applied, as it is irritating to the wounded integument.—*Medical Chips*.

SOCIETY PROCEEDINGS.

Gynecological Society of Chicago.

Regular Meeting, December 19th, 1890.

THE PRESIDENT, W. W. JAGGARD, M.D., IN THE CHAIR.

[Abstracted for THE JOURNAL.]

EXHIBITION OF SPECIMENS.

a. Polypoid Myoma. DR. C. T. PARKES presented a moderate-sized tumor removed from the vagina of a patient about 50 years old. Upon examination the pelvis was found blocked with a tumor, which showed signs of decomposition. There was no history of the discharge of the tumor from uterus into the vagina, and no history of severe bleeding. On further examination under anæsthetics a long pedicle was found attached to anterior uterine wall. Upon severing the attachment the mass was delivered.

b. Pregnant Uterus with Fibroid Tumor. Specimen presented of pregnant fibroid uterus at four-and-a-half or five months. At time of operation mass filled the abdomen as completely as pregnancy at full term. Saw patient after she had suffered severely for two weeks with pain, high temperature, considerable peritonitis, etc., indicating that interference was necessary. Pregnancy had been diagnosed previously. Two distinct tumors were evident on palpation. Examination showed pregnancy, and an operation was deemed best, which was done, pedicle being treated by extra peritoneal method. Patient recovered entirely in four weeks.

DR. JAGGARD inquired the nature of the first tumor, and whether it was thought to originate in uterus or vagina.

DR. PARKES said it was diagnosed before the operation as a submucous fibroid of the uterus. Pedicle could yet be felt coming out of cervix, and at time of operation it was found attached high up on anterior wall.

TUBAL PREGNANCY WITH TWO OVA IN SAME FALLOPIAN TUBE.

DR. CHRISTIAN FENGER offered specimen of tubal pregnancy in second month. Rupture of sac caused much bleeding in peritoneal cavity. Rupture occurred at 4 A.M., and operation was done at 11 A.M. Patient was almost pulseless, and had all signs of dangerous hemorrhage. It was the left tube, and on opening abdomen large clots and much liquid was found. Upon exploring the tubal pregnancy was found to be hanging out of ovum, and another oval body was also discovered. Patient made a good recovery. The principal point in case was the two ova, one degenerated, both in same tube. Degenerated ovum was cystic, one and one-quarter by one inch in diameter. Second ovum was ruptured and con-

tained foetus attached by umbilical cord to inside of ovum. The cystic ovum was on uterine side of ruptured one.

VELAMENTOUS INSERTION OF THE CORD.

DR. A. H. FOSTER reported case of a woman, aged 26, confined in October. Tedious and painful delivery; considerable hæmorrhage at and immediately following accouchement; child normal. Placenta was easily expelled. Cord entered membranes opposite placenta, and dividing and spreading passed to one margin of placenta, where it divided into still more branches running across its surface. One large vein was ruptured.

HEMICEPHALUS WITH HYDRAMNION.

DR. FOSTER also presented the following:—Patient having passed through a number of confinements became depressed and melancholy, and was found to have sharp anteflexion with cervical catarrh, which upon correction improved her condition, though not restoring her fully. Pregnancy was advised and sought. Upon conceiving she at once became greatly benefited. Towards end of term her large size caused discomfort and some anxiety. At time of rupture of membranes a profuse discharge of water took place, and a few strong pains expelled a hemicephalus dead foetus of about seven months. Shoulders presented. Patient made a good recovery, and is in better condition than for two years previously.

DR. W. W. JAGGARD remarked that the cases were of interest. The hemicephalus case is a typical example of cranio rachischisis. These creatures are not viable, and commonly present by the head. The second specimen is most typical.

LAPAROTOMY FOR EXTRA-UTERINE PREGNANCY TWO MONTHS AFTER DEATH OF FŒTUS AT TERM.

DR. C. T. PARKES presented specimen of entire sac and foetus removed from a case of extra-uterine pregnancy two months after child's death at term. When removed child was macerated, and showed evidence of decomposition. Sac easily broke down, especially at upper part. A portion of sac was within pelvis. Thickness of sac in places was remarkable; at some points it could be divided into several layers. The uterus was carried to left side and out of pelvis, where it could easily be felt before operation. The accidental rupture of upper, decomposed portion of sac at time of operation necessitated its entire removal. Clinical history of case is somewhat as follows: Age 21, married, no children, sterile seven years, last normal menstruation June 20th, 1889. In August had nausea and vomiting, and diagnosis of probable pregnancy was given. In October had severe pain and hæmorrhage. Recovered, but had occasional attacks thereafter. Abdomen enlarged and fetal movements were detected. On

March 1st, and for several days after, had unusual pains which subsided, and an examination developed death of fœtus. After this, and until last week in April, there was gradual diminution in size of abdomen, and apparent improvement in patient's health. At this time—last week in April—a decided change came on. Severe pains, fever, rapid pulse, etc., evidences of septic infection. March 28th decidua membrane was passed entire. On examination two abdominal enlargements could be distinguished, one the fetal tumor, and the other the enlarged and displaced uterus. Previous to March 1st the fetal head could readily be made out occupying the Douglas cul-de-sac, but after that date, through some change in the position of the fœtus, nothing but fluctuation could be felt. Digital examination per rectum permitted the fetal bones to be plainly felt, and showed but very little tissue between the rectum and the child. In summing up the diagnostic points in this case we have: 1. The ordinary signs and symptoms of pregnancy. 2. Hæmorrhage at irregular intervals during the entire period of pregnancy. 3. Pain, collapse and hæmorrhage at about the end of the fourth month. 4. Irregular abdominal, cramp-like pains, more severe and continuous than would be expected in a condition of normal pregnancy. 5. Death of fœtus at term, followed by diminution in size of abdominal protuberance and of breasts, and by cessation of lacteal secretions. 6. Irregularity of the abdominal enlargement. 7. Passage of decidua membrane. 8. Position of os uteri, forward and behind symphysis, and obliteration of cervix. 9. Very dilatable os. 10. Empty uterine cavity. 11. Pressure of the fetal head in the cul-de-sac of Douglas.

The immediate reason for operation was the evidences of general septic infection. A free abdominal incision was made and tumor exposed, which was of a dirty, spheacelated appearance, soft and easily broken down. An offensive, thick fluid discharged upon incising. Child was at once seen, breach upward, and was easily extracted, but in so doing the thin upper portion of sac was broken, allowing small intestines to protrude into sac, and fluid from sac to get into abdominal cavity. It was now thought best to remove entire sac, if it could be done. Sac was free all around, and down as far as brim of pelvis; but this cavity was entirely filled by development of sac. Tumor seemed to be covered by the peritoneum, the cæcum on the right and the sigmoid flexure on the left were intimately adherent to its walls. An incision was made through covering posteriorly, fingers introduced and covering peeled away and secured in sections by forceps. At this point of operation darkness supervened from a passing storm, and nothing could be seen in abdominal cavity, being compelled to depend alone on the sense of touch. This misfortune led to a

separation of portion of sigmoid flexure too close to its walls, interfering with its vitality and causing it to slough away on the sixth day. The right ureter failed also to be recognized, and was included in the grasp of one of the forceps, and divided. Neither of these accidents would have happened had the light been even fair. As soon as coverings were lifted off all around, the sac was easily peeled from and lifted out of the pelvis. Bleeding was slight and cavity of abdomen was thoroughly cleansed. Patient was much exhausted, but soon rallied and progressed nicely until sixth day. Urine was secreted daily, and by patient's own efforts. On removing dressings and gauze packing on sixth day fecal matter was found. Thorough irrigation was made. Fecal fistula continued until eleventh day; other progress good. Signs then of bowel obstruction came on, and patient sank rapidly, dying on the twelfth day after operation. Autopsy showed opening size of half a dollar in lowest part of sigmoid flexure. Kidney on right side atrophied. No evidence of peritonitis. Similar cases have been recorded by a number of operators.

EXHIBITION OF NEW UTERINE DILATOR.

DR. E. C. DUDLEY presented an instrument similar in appearance to a Fritsch dilator. One-half was hollow from the handle to the blade, the hollow part being convex on its inner side and fitting into the opposite concave blade. After the uterus has been dilated by other instruments, this instrument may be introduced, the blades separated, and water poured through the hollow blade from a fountain syringe connected with it. The fluid passes into the uterus through several small openings at the end of the hollow blade, and out of the uterus between the two diverging blades. The instrument has been used with considerable satisfaction for eight months.

EXHIBITION OF PERINEAL SHIELD.

DR. T. J. WATKINS showed a device to be used to protect the recently injured or repaired perineum from urine. It is inserted just below the urethra, and covers and protects the perineum. It is made of hard rubber, and easily kept clean. It renders catheterization and douching after urination unnecessary.

A CASE OF HYPOSPADIAS. (SPURIOUS HERMAPHRODITISM.)

DR. L. A. FROST of the Illinois Central Hospital for the Insane, presented, by invitation, the following: E. P., age 43, native of Germany, married to a man, mentally a mild dement. Development and general appearance masculine. Beard about six inches long; no hair on breast or limbs. Mammary slightly developed. Sexual organs imperfect. Mons veneris more prominent than general in men. Clitoris, or penis, about one and a-half inches long, with well developed

glans; movable foreskin which does not cover glans. Under side of penis covered with mucous membrane. Penis is situated between two folds of skin resembling labia majora; left labium contains a testicle which is firm and freely movable, having a small epididymis. Right labium is smaller and has no testicle. The external appearance of the hypospadias is much like that of a vagina, is one-and-a-half inches deep, and urethra opens into this about one inch above external opening. No spermatozoa can be found in urethral secretion. When the subject was a child the parents were unable to tell what the sex was, but noticing particularly that urination was like that of a female the child was dressed accordingly, given a girl's name, and subsequently married to a man.

DR. W. W. JAGGARD had seen this individual in consultation with Dr. Frost. The disposition of the patient was a practical difficulty. In the asylum was he to be placed among the males or females? He had been placed by the hospital authorities in the female department, feeling that less harm would thus result. This case is evidently one of pseudo-hermaphroditism. An autopsy only can fully determine the question. True hermaphroditism does occur, general professional conviction to the contrary notwithstanding.

FOREIGN CORRESPONDENCE.

LETTER FROM BIRMINGHAM.

Written by Dr. Fred B. Robinson, Professor of Surgery and Anatomy in Toledo Medical College.

The Meeting of the Pathological and Clinical Section of the British Medical Association—A Case of Obstetrical Paralysis—A successful Case of Cholecystotomy—Mr. Lawson Tait—Intestinal Perforations and Disturbances—The Effect of Abdominal Section on the Action of the Kidneys.

The British Medical Association met in this city January 30, with Mr. Priestly Smith in the chair. This meeting was the Pathological and Clinical Section. It was a discussion of rare interest, especially to the gynecologist and abdominal surgeon.

The first case (with patient) presented was that of an infant 4 months old, afflicted with what is called "obstetrical paralysis." At the birth of the child great difficulty arose in delivering the shoulders, and after the birth the child's right arm was almost completely paralyzed. The muscles of the arm were nearly all atrophied and the arm was rotated in a prone position. The deltoid biceps, coraco-brachialis, brachialis anticus and pronators were severely affected.

Dr. Suckling, who presented the case, considered the pathological process to be situated at the root of the fifth cervical nerve, and was due to

mechanical injury during delivery—traction on the arm. Three months' application of galvanic electricity, twice a week, had induced improvement. The prognosis, Dr. Suckling stated, was unfavorable.

Mr. J. W. Taylor presented a successful case of cholecystotomy, with especial reference to the differential diagnosis between enlarged gall bladder and kidney tumors. This elicited warm discussion from such good observers as Drs. Foxwell, May, Tait and Marsh. Dr. Taylor claimed that kidney and gall bladder enlarged must be best distinguished by the movements induced by the hand of the examiner and position of the patient. Dr. Taylor claimed that when a patient turned on the side, the kidney tumor was as plain to feel or plainer to feel than when the patient was on the back. But in an enlarged gall bladder it was different, that one could feel or palpate an enlarged gall bladder better in the horizontal or vertical position than when the patient turned on the side, and that the enlarged gall bladder was lost very much to palpation when the patient turned on the side.

Mr. Lawson Tait illustrated by a sketch on the blackboard that Dr. Taylor's rules were entirely fallacious. Mr. Tait said that one could diagnose an enlarged gall bladder from kidney tumor (right) only when he could be sure that the changed position of the patient only changed the axis of the swollen gall cyst. Otherwise, said Mr. Tait, "I defy any one to make a differential diagnosis between enlarged gall bladder and kidney tumor." Mr. Tait said that he examined his patients both in the standing and lying posture, and so far he was unable to observe any movement communicated to the gall bladder by respirations. Mr. Tait talks on the subject of cholecystotomy with an authoritative assurance born of well and hard earned experience. He is an interesting speaker in this new field, as he has such a special individuality in all his work. One feels in listening to him that he makes every one of his statements in a fighting attitude, and every statement contains a challenge. But his assertions and the truth seem to agree so closely that he absolutely forces men into thinking and investigating. His mastery in his own fields makes him the most fascinating of talkers, as he speaks apparently without any possible fear of contradiction. His methods of talk and work fire men with zeal to progress. Mr. Tait has operated about seventy times for cholecystotomy with four deaths, but I understand that three of these could not be chargeable to the operation. One of the cases died of suffocative catarrh three weeks after the operation, and two died of cancer. Such could not be directly referred to the operation.

Dr. Foxwell claimed that the large gall bladder and the kidney tumor had distinct and positive connection with respiration. He said: "I have

carefully measured the distance these tumors move during respiration, and have found that the enlarged gall bladder will move three-quarters of an inch more or less, and the kidney tumor one-half inch more or less." A claimed, disputed and undecided question arose that the enlarged gall bladder rested on the right kidney, and therefore it would be impossible to differentially diagnose them. Normal anatomy and pathology differ so much that only the conditions found in actual pathological cases were acceptable in forming conclusions. However, concrete cases demand each their own special observation, as this gall bladder may contain half a dozen parts and reach to the pubes.

The next subject brought up, and presented in an able and interesting lecture, was that of intestinal perforations and disturbances. This made your correspondent feel that he was again at home in his own green pastures, lying under his own shamrocks among his own dog kennels, where he had quieted about two hundred of the barking curs in order to find out some useful knowledge in intestinal surgery. Mr. Langley Browne first brought forward a case of death by ulcerative perforation of the duodenum. The man was brought to the hospital writhing in agony. His pain came on suddenly after a healthy life. Mr. Browne saw him some ten hours after the accident and considered him in such a condition of collapse that he was an unfit subject for operation. Some hours after the man died. At the post-mortem the abdominal cavity was found to contain fluid and material from the alimentary canal. Dr. Browne said, five physicians were present at this autopsy, and noted that the perforation could not be found at all while the alimentary tract was in the abdomen, and that it could not be discovered until the whole canal was removed from the belly and water forced inch by inch along the canal from the rectum toward the stomach. When the water neared the pylorus it was observed to trickle out of a small perforation close to the pyloric valve, in the duodenum. Mr. Browne observed that it was so difficult to find that he defied any operator to have discovered it and saved his patient. (Mr. Tait amusingly remarked that Mr. Browne did not know the skill of all operators, which created some merriment.)

It surprised us that some of these able men and skillful surgeons did not even allude to such a wonderful aid to diagnosing intestinal perforations as the simple use of simple hydrogen gas. Your correspondent, with fifteen minutes to generate a few gallons of hydrogen, and *five* minutes to find the perforation after the abdomen was open, could locate this insurmountable difficulty for Mr. Langley Browne and tell him with a scientific certainty, "there is the hole." These keen surgeons and observers are not yet familiar with this wonderful aid to intestinal diagnosis. In an in-

teresting and wide discussion of intestinal diagnosis it was not even referred to or mentioned, but I am informed that vivisection, as it is wrongly denominated, is not allowed in this country. One might as well call Koch's inoculation of animals vivisection, or breaking a young ox or colt, vivisection, as to call experiments on dogs systematically carried out under anaesthetics, vivisection. But intestinal surgery rests for its progress on experiments, and in justice to humanity these experiments should be performed first on the lower animals and not on our fellows.

Mr. Browne mentioned another case of a barmaid suddenly taken ill, and he was called and found her in a condition of collapse, unfit for operation, dying some eight hours after. The autopsy showed intestinal perforation with extravasation. Now, it is my firm belief that if these cases have laparotomy performed on them and the abdomen washed out with a few gallons of hot water it will rouse them from the shock, then with the hydrogen gas find the perforation and close it. They have no chance for life without operation and there certainly is some chance with operation.

Again, Mr. Browne stated in his lecture that whenever a person suddenly taken sick in the abdomen, and died shortly, that it was due to two causes, *viz.*, *perforation* or *hemorrhage*. This statement is very good as far as it goes. But it must be remembered that the shock to the nervous system by crushing violence on the peripheral nerve apparatus of the peritoneum and gut wall is sufficient to kill in a very short time from invagination, volvulus, or strangulation by bands and through apertures. I have seen invagination cause gangrene in ten hours or less. The gangrene is caused by the obstruction cutting off the return of venous blood while the artery continues to carry its blood to the parts, increasing the oedema. So it thus appears that death can occur very shortly, and as equally short from other forms of interstitial disturbances as from perforation and bleeding. I had, however, one young woman die in five hours from rupture of a pelvic abscess into the peritoneum.

The old idea that duodenal perforations were likely to occur after severe burns was confirmed by reported observation at this meeting. The question was asked why the ulcers occurred in the duodenum and not in other parts of the canal after burns. No direct answer arose, but it was intimated that ulcers really occurred in the stomach also, and simply extended over into the duodenum. Mr. Tait gave evidence that one of his cases of burns confirmed the theory that duodenal perforations followed severe burns, and also in cases of diabetes.

A very interesting talk followed on operations on the kidney and bladder, and also the effect that abdominal section had on the kidney. Nearly

every surgeon favored supra-pubic cystotomy rather than the perineal operation for stone in the bladder. The only objection raised against supra-pubic cystotomy was the difficulty of drainage. The objections against the perineal operation for stone in the bladder are shock to the system from cutting the bladder where the nerve supply is the greatest, of danger of cutting important structures, and of dangerous immediate and subsequent hæmorrhage.

The effect of abdominal section on the action of the kidney was freely discussed. I can remember that, years ago, the celebrated Fothergill called the attention of the profession to the fact that men should be careful to observe the real function of the kidney before surgical procedures were applied, and he noted cases in which the kidneys were not working right in which he advised that no operation should be performed, but in those very cases his advice was neglected and operation occurred, followed by death. As gynecologists we have learned to day that Fothergill was right, but also we think that operations on the *peritoneum* have special dangers in relation to the kidney. I am thoroughly convinced that surgical procedures on the peritoneum are more efficacious in morbidly disturbing the kidney secretion than on almost any other bodily organ. Whether the effect lies in the wounding of the rich and even luxuriant peripheral nerve apparatus which lies thickly scattered in the wall of the peritoneum, I am not prepared to say.

Dr. Foxwell said that he had studied the matter from two points. He said that he had finally satisfied himself that albumen was not a very reliable standard to go by, and especially a single examination of the urine was useless to indicate when the operations could be performed safely. He thought that the best standard to indicate whether abdominal section should be performed was the amount of *urea* secreted daily. He said that abdominal section should not be performed with less *urea* secreted than 200 to 160 grains daily.

Mr. Bennett May observed that it was especially necessary to observe the rules of the secretion of *urea* in kidney extirpation, as one might remove the very kidney which contained about all the secreting substance that the patient possessed.

Mr. Tait thought that the rules relative to albumen and *urea* were more important in kidney extirpation than other abdominal sections, but he was quite anxious to secure definite laws with regard to the amount of substances secreted by the kidney that would indicate abdominal sections with safety.

Mr. Langley Browne showed several large stones removed by perineal operation from the bladder, and some kidneys which were largely filled in the pelvis with numerous and large calculi.

Dr. Christopher Martin, assistant to Mr. Lawson Tait, demonstrated some specimens of abdominal tumors which had been rotated on their pedicle. Dr. Martin showed one that was gangrenous from the twist in the pedicle, and which was successfully removed by Mr. Tait. He showed another tumor which had a pedicle twisted like an umbilical cord, but which was not strangulated. The rotation had not progressed far enough to mechanically occlude the vein or artery. This tumor was also successfully removed by Mr. Tait. The tumor which was strangulated had occurred in Dr. Martin's practice. Dr. Martin examined the woman and found a tumor in the abdomen, and he was called to see her three days after, when he found the tumor had increased to double the size. She was then very sick. The sudden increase of the tumor induced the diagnosis of axial rotation of a tumor with hæmorrhage into it. Mr. Tait was called in consultation with Dr. Martin, when it was decided to remove the tumor. The above named gentlemen operated, and found the tumor twisted on its pedicle and gangrenous. The woman made an easy recovery.

Birmingham, Eng., Feb. 2, 1891.

DOMESTIC CORRESPONDENCE.

Did a Majority of the Board of Trustees Vote for the Removal of the Journal to Washington?

To the Editor:—The general impression seems to have gone abroad that the *majority* of the Board of Trustees were in favor of the removal of THE JOURNAL to Washington. If I am not mistaken this is not in accordance with the facts. If I am mistaken I desire to be corrected.

As I understand, Dr. Garcelon, of Maine, was not present at the Washington meeting of the Trustees, and was not represented by proxy. Dr. Moore was represented by proxy directed to Dr. Hooper, the President of the Board, but without an expression of preference. The same of Dr. Dawson, of Ohio. Of the six members present I understand that Dr. Hamilton, of D.C., Dr. Love, of Missouri, and Dr. Shoemaker, of Pennsylvania, were in *favor of immediate removal*; that Dr. Hollister of Illinois, was opposed to removal; that Dr. Nelson, of Tennessee, was in favor of submitting the question to the Association, and that the President, Dr. Hooper, of Arkansas, would favor the removal to Washington provided it was the expressed wish of the majority of the members of the Association.

If my information is correct it certainly cannot be affirmed that a majority of the Board are in favor of removal!

H. MARTYN SCUDDER, M.D.

Chicago, Ill.

A Pan-American Medical Congress.

To the Editor:—I beg leave to announce to the members that it is my intention to move at the Washington meeting, 1. That the American Medical Association extend to the profession of the Republics and Colonies of the Western Continent an invitation to assemble in this country in an *International American Medical Congress*; and, if this resolution be adopted, then, 2. That the Nominating Committee be instructed to report a committee of one from each State and territory, and one each from the Army, Navy, and Marine Hospital Service, to whom shall be referred the time, place, and permanent organization of the proposed Congress.

There is substantial reason why this step should be taken and why the proposed Congress should be held. Polite learning has always followed in the wake of commerce. The recently established and rapidly developing politico-commercial relations between the United States and the other countries of the two Americas must, in the nature of things, bring about an interchange of the sciences and arts. Among these latter, medicine in its broad sense will be the first to be forced into the foreground. The restrictions which are placed upon commerce in the interest of health make it imperative that problems of naval hygiene and international sanitation be discussed and definitely settled. The question of epidemics, their causation, propagation and habitat, becomes, as never before, one fraught with imminent commercial and vital importance. Pressing hard upon both these broad and comprehensive themes, indeed forming integral parts of them, is the great and developing department of bacteriology. Through the medium of this newest of medical departments all branches of medicine and surgery have become intimately correlated. Thus we discover at once that, between the United States and the other countries of the Western Continent there exists a commercial interest in all topics which can engage the attention of a Medical Congress.

The medical schools of Latin America are generally endowed and enjoin a curriculum which insures the scholarship of their alumni. The recent graduates, however, go to the European schools for advanced study. If the profession of the Southern Republics could be induced to visit the United States and thus become familiar with the clinical and educational resources of our great cities the result would doubtless be an increased enrollment from these countries in both our under- and post-graduate schools. On the other hand our own students desirous of prosecuting their studies in a language which shall have a commercial as well as a classical importance may find it profitable to spend a season among the hospitals and laboratories of Havana, Rio Janeiro and Buenos Ayres.

I beg to state that early last winter I opened a personal correspondence with distinguished medical gentlemen of Mexico, Central America and South America, requesting their individual views as to the expediency of such a Congress and that the replies so far received are uniformly favorable.

My apology for bringing this matter up before the assembling of the Association must be found in the importance of the contemplated action and in the further importance of having the delegates come to the meeting able to reflect in some measure the sentiments of the profession whom they represent.

CHARLES A. L. REED, M.D.

Cincinnati, April 6, 1891.

Phymosis.

To the Editor:—Page 271 in No. 8 of THE JOURNAL contains an article on "Painless Circumcision" by Dr. G. W. Overall, with which I was much pleased. It is a great step in advance of the old method of giving chloroform, which several times in my practice endangered the life of the little patient. Since then I have to a certain extent followed the method of Dr. Overall. That is, I have used a 20 or 30 per cent. solution of cocaine and injected 10 or 15 drops with a blunt pointed glass syringe into the preputial orifice, pressing the prepuce tightly around the end so as to retain the fluid, after removing the syringe. I churned the fluid cocaine so as to come in contact with the entire mucous membrane for ten or fifteen minutes. I at the same time sprayed over the entire integument where the circumcision was to take place an anesthetic solution consisting of

R. Chloroform, ʒiiss.
Ether sulphuric, ʒiv.
Menthol, grs. xv. ʒj.

until I felt satisfied that complete anesthesia of the part was produced. I now begin the now painless operation and so far I have not been disappointed in that respect. A fine catgut interrupted suture will soon unite the edges. Dress with iodoform gauze and bi-chlorinated cotton, and you will have every reason to feel satisfied with the best method of operating for phymosis. Tepid water sprays and dressings will keep down all local inflammation should there be much.

If the operation now required for enuresis of long standing a little medication may be necessary for a week or two after the operation, in that case I have found excellent results from the following:

R. Atropine sulph. gr. ij.
Aque distil. ʒj. ʒj.

Sig. One drop for each year of age of the child, at 4 and 7 P.M. Increase the dose if no effect is produced in one week.

All nervous irritation, spasms, convulsions in the little sufferer will generally rapidly subside.

I will close by saying that all male children troubled with enuresis and all other nervous dis-

eases of a reflex nature should never be prescribed for unless the physician is satisfied from *actual observation* that no condition of phymosis exists. If there is, circumcision is the only radical cure.

B. STORCH, M.D.

Alta, Iowa.

SPECIAL CORRESPONDENCE.

Shall The Journal be Removed to Washington?

THE VOICE OF OUR MEMBERS AS SHOWN BY A VOTE OF THE SAME ON THE QUESTION OF THE REMOVAL OF THE JOURNAL FROM CHICAGO TO WASHINGTON.

As straws show which way the gentle zephyrs blow;
Thus Votes, the will of our Association show!

The agitation on the part of some of the Trustees, which contemplates a removal of THE JOURNAL of the Association from Chicago to Washington, was scarcely announced, before a general feeling of opposition was clearly evident in a large majority of the more active members of the entire Association—North, South, East and West. But how to obtain an expression from the members regarding such a movement, and, at the same time, put in force the will of the majority of the same under all the circumstances, was a perplexing question. The Association being made up of permanent members and delegates, the former having no vote and the latter having become extinct by virtue of their adjourning *sine die*, there was no official way by which an expression of the will of the members could be obtained prior to the coming meeting. In other words, our Association is like a chrysalis, so far as any official action of its members is concerned between each annual meeting. This being the case it was patent to every one that no official action could be taken on this vital question by the members before the meeting at Washington. Yet this did not prevent any permanent member from canvassing the field and ascertaining as nearly as possible the feelings of the members regarding the proposed removal of THE JOURNAL to Washington. The result was that after several consultations with numerous *friends* of THE JOURNAL who were simply high privates in the rear ranks of our membership, I decided to conduct a complete canvass of the members and ascertain their individual opinions on this most important question. Consequently I prepared and mailed, or had mailed, to each permanent member of the Association, the following circular letter with which I enclosed a postal card addressed to myself, or such others as were assisting me, on which the following blank was printed:

My Dear Doctor:—You are no doubt aware long ere

this that an effort is being made to remove The Journal of the American Medical Association from Chicago, Ill., to Washington, D. C. As I am desirous of obtaining a free expression from the leading members of the Association, of their *candid opinion* in regard to this all important question, I herewith enclose you a blank postal card on which I will ask you to kindly inform me whether you are *in favor* or *opposed* to this movement to change the place of publication of our National Journal from the Western Metropolis to the National Capital; to which we will be pleased to have you add the principal reason "for the faith that is within you."

Trusting that I may have the honor to receive an early reply through your courtesy, I remain,

Sincerely and Fraternaly Yours.

R. HARVEY REED.

Mansfield, O.

1891.
Dear Doctor:—In answer to your inquiry of 1891, regarding the removal of "The Journal" of the American Medical Association from Chicago to Washington, it is, in my opinion, to the best interests of the "Journal" to have it
Briefly my reasons for the above opinion are
(Signed) M.D.

In this work I was ably assisted by Dr. T. D. Crothers, of Hartford, Conn., who sent out the same circular to the members in the Eastern States, and received and recorded their views. Likewise I was assisted by Dr. C. E. Beardsley, of Ottawa, O., who looked after the votes in Ohio, and Dr. John F. Fulton, of St. Paul, Minn., who canvassed Minnesota, and Dr. T. M. Hood of Weston, W. Va., who secured the votes for his State; all of which votes have been carefully recorded on tally sheets prepared for that purpose, of which the following is a *fac simile*, giving the name, his postoffice address, together with his vote, all of which is backed by his reply on the postal card or letter he returned, which has been carefully filed away for future reference.

TALLY SHEET.—Showing the Record of the Returns of the Votes taken, with Reference to the removal of "The Journal" of the American Medical Association from Chicago, Ill., to Washington, D. C.

Returned to Dr. R. Harvey Reed, Mansfield, O., by
Dr. of St.
. Post Office, State of
. Division.

Names	Post Office.	State.	Vote for Chicago	Vote for Wash.	Remarks

After recording the votes on these tally sheets we journalized them, so to speak, into States, giving the total number of members in each State, to each of whom a circular had been sent; the total number of votes received from each State; the total number for Chicago; the total number for Washington, and the total number for other places, or those who were undecided or had no preference, all of which is clearly shown by the following tabulated report. This report was closed on the 8th of April, notwithstanding we were receiving quite a number of votes daily, and have continued to receive them ever since it

was closed, these unrecorded votes being largely in favor of Chicago.

Votes with no address		8	3	4	1
Totals	3,911	2,210	1,892	209	118

Number not reported, 1,692.

It will be observed, by studying this table, that there are eight States which have a membership of over 200 each, and they stand in the following numerical order :

Name of State.	No. of Members.	No. Votes Returned	Chicago.	Washing- ton	Scat- ter g.
Illinois	435	274	271	1	2
Pennsylvania	422	171	139	26	19
Ohio	299	244	210	21	13
Indiana	277	169	154	4	1
New York	275	127	91	32	14
Tennessee	232	104	90	11	3
Iowa	226	149	145	4	1
Missouri	217	115	99	11	5
Totals	2,383	1,366	1,199	109	58

In these eight States you will observe there is a total membership of 2,383, and out of this number 1,366 voted : 1,199 of which are in favor of Chicago, whilst only 109 are in favor of Washington, and 58 are undecided. But, were all those voting for Washington and scattering to join together with those who did not vote at all,

to vote for the Capital City, Chicago would still have a majority of the whole.

By a further study of this table it will be observed that Illinois stands first numerically in the replies to our circular, Ohio second, Pennsylvania third, Indiana fourth, Iowa fifth, New York sixth, Missouri seventh, and Tennessee eighth.

In regard to the vote for Chicago, Illinois also stands first, Ohio second, Indiana third, Iowa fourth, Pennsylvania fifth, Missouri sixth, Tennessee seventh, and New York last.

In the vote for Washington this is reversed, and New York stands first, Pennsylvania second, Ohio third, Missouri and Tennessee equal for fourth place, Indiana sixth, Iowa seventh, and Illinois last, with only one vote for the National Capital.

As to the scattering and undecided vote Pennsylvania ranks first, New York second, Ohio third, Missouri fourth, Tennessee fifth, Illinois sixth, with Iowa and Indiana on an equal footing for seventh place.

Again, you will observe that 88 per cent. of the entire vote in these eight States is for Chicago, and only 8 per cent. for Washington, with 4 per cent. undecided or for some other city.

But when you consider that out of 3,911 members all but 1,692 voted on this question, and that out of the 2,219 votes cast 1,892 were for Chicago, and only 209 for Washington, and but 118 scattering and undecided, or, in other words, over 85 per cent. of all the votes cast are in favor of THE JOURNAL remaining at Chicago, and only 9 per cent. are in favor of it being removed to Washington, whilst only a fraction over 5 per cent. are either undecided or voted for some other city, it shows that the evidence is overwhelmingly in favor of Chicago, and against the removal of THE JOURNAL to Washington.

It does not seem possible that any Board of Trustees would dare to attempt such a hazardous undertaking against the wishes of such a large percentage of their constituents, and especially so when we remember that 45 of the heaviest advertising patrons of THE JOURNAL are decidedly in favor of it remaining in Chicago against 15 of the lighter advertising patrons who favor the National Capital, as reported in last week's Journal.

The marked indifference manifested by the profession in the District of Columbia is worthy of some attention. Out of a total membership of 84, only 36 voted on this question at all, or in other words, six less than half of the total membership expressed any opinion whatever, and ten of these were in favor of THE JOURNAL remaining at Chicago, whilst five were indifferent, and but 21 out of 84, or to be more explicit, only 25 per cent. of the entire membership living in Washington and the District of Columbia expressed themselves in favor of this change ; this

fact alone should cause us to pause a moment at least, and ask why all this indifference regarding the removal of *THE JOURNAL* on the part of the profession of our Capital City, if they favored such a change and thought it for the best interests of *THE JOURNAL*?

We trust that the facts we have presented to you in the above table, which have been procured at no small amount of labor and expense, will serve to satisfy every reader of *THE JOURNAL*, as to what the popular feeling of the members of our Association is, regarding this proposed removal, which has been so thoroughly discussed, both pro and con, in *THE JOURNAL*, that no reader of the same could have voted other than intelligently on this question.

We trust that every State, district and local medical society in our country, will see to it that a full representation of their delegates are present at the coming meeting at Washington to vote their convictions on this question, and also to see to it that the member of your nominating committee in each State is true to your interests, and a man who will favor the election of new members on the Board of Trustees who are in full accord with the wishes of their constituents, on this important issue, and thus forever settle this needless and unprofitable controversy which has evidently been sprung on the members by a clique of medical politicians.

Very respectfully submitted.

R. HARVEY REED.

Mansfield, O., April 13, 1891.

ACTION OF THE GOLDEN BELT DISTRICT MEDICAL SOCIETY OF KANSAS.

At a regular meeting of the Golden Belt District Medical Society of Kansas, held at Topeka, Kansas, on April 9, 1891, Dr. William B. De-wees, of Salina, moved the following resolution which passed unanimously, viz.:

WHEREAS, The Board of Trustees of *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*, at a recent special session in Washington, D. C., adopted a resolution favoring the change of the home of *THE JOURNAL* from Chicago to Washington, and

WHEREAS, This is a question which the Association will be called upon to answer at its next meeting at Washington, D. C., in May, 1891, and

WHEREAS, We believe it to be for the best interests of *THE JOURNAL* and the Association, that the office and place of publication of *THE JOURNAL* should not be removed. Therefore, be it

Resolved, That the delegates from this Society to the next meeting of the American Medical Association are hereby instructed to vote for no change to be made in the location of *THE JOURNAL*, and further, be it

Resolved, That we urge all Kansas delegates to vote against its removal.

F. B. BROWNE, M.D., Secretary.

To the Editor:—While in favor of Chicago, as the publishing centre for *THE JOURNAL*, I think

the better plan, in view of the present controversy, would be to *abolish THE JOURNAL altogether*. It has never supplied a want in medical journalism, and it can never be a universal success, because it cannot unite and harmonize the varied and various interests of this immense breadth of country. Comparisons with the *British Medical Journal*, so often made in these columns, are entirely illogical when we take in consideration the small area of England, and the difference in the character of the medical profession in the two countries. There are plenty of medical journals in this country to-day which would publish the papers that are read at our meetings to much greater advantage to their authors, and much sooner, than *THE JOURNAL* can or has done.

I am in favor of abolishing *THE JOURNAL*, which is in most cases but a late edition of the Association proceedings. In its stead I am in favor of having the Transactions of each Section published separately in good shape, as soon after the meetings as possible, and sent to the members, each member designating the Section whose Transactions he wishes. In this way each member would have in a complete and compact form the proceedings of the Section he is most interested in, always ready for reference, and a useful addition to his library. Increase the membership by reducing the annual dues, and abolishing *THE JOURNAL*. Publish the Transactions of each Section separately. Neither Chicago, nor Washington, but union forever.

ERIC E. SATTLER, M.D.

117 Garfield Place, Cincinnati, O.

To the Editor:—Remove *THE JOURNAL* to Washington? No! Remove Washington to *THE JOURNAL*.
E. D. MOFFETT, M.D.
Indianapolis, April 9, 1891.

To the Editor:—Let *THE JOURNAL* remain where it is—at least for the present.

JOHN C. SUNDBERG, M.D.

San Francisco, Cal.

To the Editor:—I have been interested in the correspondence pro and con on the proposed removal of *THE JOURNAL* from Chicago to Washington. Unless some very important personal interests are to be served, no tangible reason appears why the change should be made.

One might have a certain National pride in the location of *THE JOURNAL* in Washington because it is the Capital of the Nation; but sentiment in such an enterprise should give way to utility. There are decided practical advantages in a great medical centre, which Washington can never have. It is a question whether the quality of *THE JOURNAL* would be satisfactory to the whole profession if it were made subject to the political and bureaucratic influences of the Capital.

As a permanent home for THE JOURNAL Chicago would improve; Washington would not. Of all the great medical centres in the country Chicago has the minimum average distance from subscribers and contributors,—an advantage which will increase with time.

The political and commercial centres of gravity of the United States are moving westward with a force which is irresistible. The question is whether THE JOURNAL would profit by going *against* such a force.

E. C. DUDLEY, M.D.

70 Monroe St., Chicago, April 2, 1891.

To the Editor:—Let THE JOURNAL remain in Chicago.

GEO. R. HIGHSMITH, M.D.

Carrollton, Mo.

To the Editor:—Please enter me as a voter to let THE JOURNAL remain at Chicago. There have been many valid reasons assigned by your correspondents why it should not be removed, but I have seen none so far to the contrary.

T. B. GREENLEY, M.D.

West Point, Ky., April 6, 1891.

To the Editor:—The American Medical Association acted wisely when it exchanged the annual volume of Transactions for the weekly JOURNAL; and displayed equal wisdom in locating the plant for its publication in Chicago.

The growth of THE JOURNAL has been in keeping with the growth of its home, and both bid fair, in the near future, to stand without rivals, the pride of the American people and the admiration of the world.

Each member of the Association, may with the writer feel proud that his vote helped to create THE JOURNAL and gave it a home in the grandest city, for its age, that the world has ever seen: while to all, it should be a source of regret, amounting almost to sorrow and shame, that so small a personal matter, a mere whim of a vain and over-selfish brain, should be permitted to cause such a commotion and menace the prosperity and very life of THE JOURNAL. THE JOURNAL belongs to the Association, and to the ordinary mind, it looks preposterous that any measure so potent for evil, so uncalled for, as the removal of THE JOURNAL to Washington City, should for one moment be seriously considered, or much less be carried into effect or attempted to be, without the consent of a clear majority of its members.

While trickery may be permitted in politics, it is certainly too contemptible to be allowed a place in the deliberations of so august and honorable a body, as the American Medical Association, or to figure conspicuously in its transactions; striking as it does, in this case, at the prosperity and welfare, yes at the very vitality of the Organ of the Association; and all for mere selfish ends.

This is certainly a case of "pure cussedness," and having diagnosed it correctly we are certainly competent to treat it with success, and I would recommend heroic dosage that would at once eliminate or suppress it—"sit down on it"—and ineffectually suppressed in that way it will not soon manifest itself again.

But there has already been too much time spent and too much space in THE JOURNAL wasted in discussing the removal inasmuch as not one in every twenty members really desire it; while no one urging its removal ever has offered, or probably ever will, or can offer, a single reason justifying its removal to Washington while the reasons assigned for its remaining where it is have been both abundant and overwhelming in force.

A. J. SCOTT, A.M., M.D.

Loudonville, Ohio, April 7, 1891.

Editorial Opinions of the Medical Press.

The arguments used in favor of the removal of The Journal of the American Medical Association to Washington, are somewhat peculiar. The arguments, that the personal influence of Dr. N. S. Davis is too marked, and that the Chicago profession have a monopoly of its contents, or that it is conducted in the interest of a clique, are not very well substantiated. If The Journal were liable to fall into the hands of a select coterie, nowhere would it be more possible than in Washington.—*Physician and Surgeon*, March, 1891.

Shall The Journal be removed to Washington? The call for a general expression of opinion on the above question, was prompted by the knowledge that the members of the profession are very largely interested in The Journal, and as integral parts of the American Medical Association they should have a voice in the debate. The arguments for and against the removal have been more numerous than convincing, and in many instances have degenerated into mere partisan exhortations. It should be remembered that this publication represents the National Association, and that sectionalism has no right to be heard. Any argument, therefore, based on the prior claims of the medical men of any location or district, is out of place.

Of all the reasons given as to why The Journal should remain in Chicago (aside from the fact that Chicago is its present home), one only appears to have weight. This is the geographical situation of that city, which is nearer the population centre of the country than most other eligible places. But The Journal is the official organ of an Association that meets only once a year; it is the means of publication of the transactions of these yearly meetings, and half of the articles presented are six months old or more before they can appear in print. The sole advantage of a central location is the delivery of The Journal a few hours earlier to most of its subscribers, an advantage that under the circumstances of its publication does not seem to be of very great importance.

The arguments in favor of Washington as the seat of publication are two: First, that as the Capital City of the United States, as the centre of government, Washington is a peculiarly appropriate home for the publication of a National journal. This is mere sentimentalism. Washington is the political centre of the country, and nothing more. It is not the art centre, nor the scientific centre, nor the educational centre, and it certainly is not the medical centre of the United States. The second argument, that the National Library and Museum at Washington offer advantages lacking in other places, is worthy

of more consideration, but it is not clear that some other localities may not equal or even excel Washington in this particular; moreover, the history of The Journal does not show any need of such facilities; it is not of that ultra-scientific character that demands resources of this kind.

It seems to us there are but two deciding factors to be considered in this question. One is the facilities offered by a large city for the mechanical part of the publication. This demand may be satisfied in any locality that provides a sufficient printing establishment, and where the postal service is good. The other and most important consideration regards the editorial equipment. The success or failure of The Journal depends directly upon the editor, and The Journal should be published in the locality where it can command the very best editorial talent be it Chicago or Washington, Boston or New Orleans, New York or St. Louis, or Arcot, Tennessee.—*Pittsburgh Medical Review*, March, 1891.

This subject has been pretty thoroughly discussed from one point of view, namely, whether the interests of The Journal and the needs of its readers will be subserved by the proposed change. The argument stands about as follows: Drs. A., B. and C. believe The Journal should be removed to Washington, because they wish it; whereas Drs. X., Y. and Z. desire it to remain in Chicago, because their interests demand it. Which of these parties succeeds in fortifying this principal argument by the strongest accessories in the shape of votes, will be shown at the coming meeting of the Association.

But there is another aspect of the case, which has not, we believe, received any attention. How will the removal affect the interests of Chicago?

To the present resident staff of The Journal this would seem a matter of course, as it would seriously incommode them to be compelled to remove to Washington. They form but a small element in the Chicago profession, however, and when we eliminate the question of personal interest, we cannot come to any other conclusion but that the removal would be a good thing for Chicago.

The Journal is not, and must not be, in any sense a local journal. It is national; and any attempt to make it a representative of Chicago medicine would be met with a howl of reprobation from all quarters. And yet, as the only professional journal published in that city, it blocks the way for what Chicago needs, a strong and well-supported weekly medical journal. Chicago is now the second city in this continent. Its business interests are even greater than its population, proportionately. Its physicians number over 2,000; active, progressive and cultured men. But in medical journalism it is represented by three monthlies, published by two manufacturing drug firms and one surgical instrument house. Very good journals they are, and very well edited; but is it not a disgrace that the medical profession of that city has no journal of its own, but is contented to take its literature from such sources?

If The Journal were to remove to Washington, there would be an opportunity for Chicago's warring cliques to unite in the production of a good medical weekly that would worthily represent the profession of that city.—*Times and Register*, March 21, 1891.

Our readers all know that the American Medical Association has a journal, a real live publication of its own, and that The Journal is managed by a Board of Trustees, and that the Trustees have just more than stirred up matters by openly proposing to move the place of its publication from Chicago to Washington. Praises and denunciations of the Trustees and The Journal have been as general as the rustling of the leaves in Autumn. Every member of the Association is a stock-holder, and realizes fully the grave responsibility that rests upon

him in that capacity, and away down deep in the innermost recesses of his consciousness he believes he knows more about the creation and running of a weekly medical journal than that whole Board of Trustees put together, and any number have gone so far as to argue that The Journal ought to remain in Chicago because of its superior mail facilities, or that it ought to go to Washington because that city isn't a medical centre and hasn't got a medical journal of any kind, and would, on that account, be free from influences. Such arguments are downright heavy-weights in the minds of the doctors who live at crossroad villages and receive a mail but once or twice a week, and who hesitate about sending their sons to a large city for fear of their contact with the sin and wickedness that stalks all around, or lies in ambush for just such sons as theirs.

As for mail facilities in these days of wonderful works, the Journal of the American Medical Association can be just as rapidly distributed to its subscribers if mailed at Kokomo, Lebanon or Kankakee, as if mailed in Chicago; and as for influences, why bless the innocent souls of the Oskosh and Podunk members, Washington is full of them. There is the Columbia Medical College, that is just as much a medical college as the Chicago Medical College; and the Columbia Hospital; the Surgeon-Generals of the Army, Navy and Marine-Hospital Service, three of them, and all influences of the most potent kind. A National Medical Library is there also, one that belongs to the United States, although its manipulator sometimes has spells in which he don't think so, and just placards it "closed for repairs." Why there are actually more influences in Washington than there is wind in Chicago. Another argument, and the one most leaned upon by those favoring Washington is, that it is the Capital of our Nation. This is true, and it means much, but Washington is in no sense a metropolis, nor is it near the centre of population. We think the latter a factor of the very greatest importance. We regard the centralization of goodly numbers in active medical society work as a barometer that never fails to tell of the quality and character of the men who support medical journals.

The New England profession has its Boston *Journal*, the New York profession, their *Record and Journal*, and in Philadelphia, the *Reporter, News, Times and Register*, not counting the monthlies. These are all well and ably sustained; and not one of the proprietors of those journals wants the Association Journal one mile nearer to them than it now is. This journalistic lukewarmness has extended to the subscribers and supporters of those publications. The local medical profession of Washington, to their credit and honor, it must be said, have as a body been loyal sustainers of the American Medical Association. Furthermore, it cannot be charged against them that they have engaged in any intrigues to secure the transfer of the journal publication office to their city. While the question has been of the most vital interest to the Chicago profession. The discussion seems to have done great good in stimulating them to activity in good works that was not before manifest; in fact there is an awakening to a realizing sense of the good thing they have enjoyed in the location of the Association Journal in their city.—*Cincinnati Lancet-Clinic*, March 21, 1891.

DR. J. L. FULLERTON, Secretary of the Medical Society of the State of West Virginia, died March 3, near Charleston, W. Va.

SURGEON ABEL F. PRICE, U. S. N., formerly of the Naval Dispensary, Washington, D. C., has been ordered to the Monongahela, as also Assist. Surgeon S. G. Evans, from the Naval Academy.

ASSOCIATION NEWS.

American Medical Association.

RAILROAD ARRANGEMENTS.

We are able to announce that arrangements have been made with the Pennsylvania Central, the Baltimore and Ohio, and the "Big Four," the three great through lines from Chicago to Washington, by which Physicians and their families can obtain transportation with return tickets at one and one third rates.

Dr. Atkinson, the Secretary of the Association, informs us that the Western Passenger Association has refused to grant commutation upon the following roads: the Atchison, Topeka & Santa Fe, Burlington, Cedar Rapids & Northern, Burlington & Missouri, Chicago & Alton, Chicago & Northwestern, Chicago, Burlington & Northern, Chicago, Burlington & Quincy, Chicago, Milwaukee & St. Paul, Chicago, Rock Island & Pacific, Chicago, St. Paul, Minneapolis & Omaha, Chicago, St. Paul & Kansas, Hannibal & St. Joseph, Kansas City, St. Joseph & Council Bluffs, Illinois Central, Iowa Central, Milwaukee & Northern, Milwaukee, Lake Shore & Western, Minneapolis & St. Louis, Missouri Pacific, Rock Island & Peoria, Sioux City & Pacific, St. Louis, Keokuk & North Western, St. Joseph & Grand Island, Union Pacific, Wabash, Wisconsin Central. It may therefore be desirable for those who propose to go to Washington to secure tickets to Chicago, St. Louis or Cincinnati, and from thence avail themselves of the special rates.

We have received a further communication from Dr. Atkinson in which he states that all who buy tickets over the roads which have agreed to the certificate plan must obtain a certificate of the agent at the time of purchase. "This signed by me at Washington enables him to obtain a return ticket at one-third full rate." *No rebate will be allowed otherwise.* The following roads are all that agree to any reduction:

Trunk Line Association, comprising the Grand Trunk, New York Central & Hudson River, West Shore, N. Y. Central & Western, New York, Lake Erie & Western, Delaware, Lackawanna & Western, Lehigh Valley, New Jersey Central, Phila. & Reading, Pennsylvania, Baltimore & Ohio, Chesapeake & Ohio.

New York & Boston Lines Passenger Committee, comprising the New York, New Haven & Hartford, Old Colony, Old Colony Steamship Co., New York, Providence & Boston, Providence & Stonington S. S. Co., New York & New England, Norwich & New York Transportation Co.

Southern Passenger Association, comprising the Atlantic Coast Line, Atlanta & West Point, Brunswick & Western, Charleston & Savannah, Central of Georgia, East Tennessee, Virginia &

Georgia, Georgia Pacific, Georgia Southern & Florida, Jacksonville, Tampa & Keywest, Norfolk Western, Penna. South of Washington, Port Royal & Augusta, Raleigh & Gaston, Richmond & Danville, Richmond, Fredericks & Potomac, Savannah, Florida & Western, Sea Board & Roanoke, Shenandoah Valley, South Carolina, Western & Atlantic.

Central Traffic Association, comprising the territory bounded on the East by Pittsburg, Salamanca, Buffalo & Toronto; on the North by the line of the States of Ohio, Indiana & Illinois to the north line of Cook County; on the West by the west line of Cook County and the Illinois & Mississippi Rivers to Cairo, including Burlington, Quincy, Hannibal and St. Louis; and on the South by the Ohio River, but including points on either side of that river.

INSTRUCTIONS TO DELEGATES.

1. Each person must purchase not more than three days prior to the date of the meeting nor later than three days after the commencement of the meeting, a first-class ticket, either unlimited or limited, to the place of meeting, for which he will pay the regular tariff fare, and upon request the ticket agent will issue to him a certificate of such purchase. Form 2, properly filled up and signed by said ticket agent.

2. If through tickets cannot be procured at the starting point, the person will purchase to the nearest point where such through tickets can be obtained, and there repurchase through to place of meeting, requesting a certificate properly filled out by the agent at the point where repurchase is made.

3. Tickets for the return journey will be sold by the ticket agents at the place of meeting at one-third the highest limited fare, only to those holding certificates (Form 2), signed by the ticket agent at point where through ticket to the place of meeting was purchased, and countersigned by the secretary or clerk of the convention, certifying that the holder has been in attendance upon the convention.

4. It is absolutely necessary that a certificate be procured, as it indicates that full fare has been paid for the going journey, and that the person is therefore entitled to the excursion fare returning. It will also determine the route via which the ticket for return journey should be sold, and *without it no reduction will be made*, as the rule of the association is that "No refund of fare can be expected because of failure of the parties to obtain certificates."

5. Tickets for return journey will be furnished only on certificates procured not more than *three days* before the meeting assembles, nor later than *three days* after the commencement of the meeting, and will be available for continuous passage only; no stop over privileges being allowed on tickets sold at less than full fares. Certificates will not be honored unless presented within *three days* after the date of the adjournment of the convention.

6. Ticket agents will be instructed that excursion fares will not be available unless the holders of certificates are properly identified, as above described, by the secretary or clerk, on the certificate, which identification includes the statement that one hundred or more persons who have purchased full fare tickets for the going passage, and hold properly receipted certificates, have been in attendance at the meeting.

The certificates are not transferable, and the signature affixed at the starting point, compared with the signature to the receipt, will enable the ticket agent to detect any attempted transfer.

Section on Materia Medica and Pharmacy.

The Section on Materia Medica and Pharmacy will meet for organization at 2:30 P.M., on Tuesday, May 5, at a place to be named by the Committee on Arrangements of the American Medical Association.

In conformity with the report of the Committee on Conference, adopted at the last session, the American Pharmaceutical Association, by invitation, has appointed a Committee of twenty-five of its leading members, representing all sections of the United States, to attend this Section and contribute to its scientific proceedings. The afternoon of the second day will be devoted to the consideration of the United States Pharmacopœia, the discussion to be opened by Professors H. C. Wood, M.D., and Joseph P. Remington, Ph.G. As a number of members of the Committee on Revision of the U. S. Pharmacopœia will be present, such discussion cannot fail to be interesting and valuable.

Members of the American Medical Association engaged in teaching pharmacology are especially requested to manifest their interest in this new Section by registering their names as members and by contributing to its proceedings.

Titles of papers, with brief abstracts of contents, should be sent at once to the office of the Chairman, No. 218 S. Sixteenth St., Philadelphia, in order that they may be published in the official programme. Papers should not occupy more than fifteen minutes in delivery.

FRANK WOODBURY, Chairman.
W. G. EWING, Secretary.

NECROLOGY.

DR. HENRY WILLIAM STEPHENS of Brooklyn, N. Y., died February 22, in consequence, as is believed of an autopsical injury or infection. He was only thirty-three years of age and had been only eight years in the profession. He was a native of Saratoga Springs, a graduate of Williams College and of the College of Physicians and Surgeons, New York. After graduating he spent two years as interne in the New York Hospital, whence he went to Cheyenne and there remained in practice until last October. He then came East and, having made his residence in Brooklyn, was soon thereafter chosen assistant pathologist to the hospital above named. In the latter part of January, he had occasion, in the performance of his round of duty, to participate in an autopsy in a hydrophobic case, although at that very time having an unhealed dissection-wound and some inflammation of the left arm resulting therefrom. The old sore was broken in upon in the course of the hydrophobic autopsy, and Dr. Stephens deemed it wise to put himself under the treatment of Dr. Gibier of the Pasteur Institute. The

inoculation treatment was yet in progress when the ill-fated young pathologist was confined to his house by symptoms of peripheral neuritis. His sufferings were intense and were succeeded by paralytic symptoms, which were progressive and extended finally to the muscles of respiration, to remedy which resort was had to artificial respiration, maintained for over sixteen hours by the young man's medical friends and students from the New York Hospital. Consciousness persisted until a few minutes before the end. His loss is one not lightly to be measured, for he united to high native ability, a well trained judgment, as well as industry, courage and fidelity to duty.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from April 4, 1891, to April 10, 1891.

Capt. Jno. Van R. Hoff, Asst. Surgeon, now in New York City, on leave of absence, is assigned to duty as an additional member of the board of medical officers constituted by par. 18, S. O. 82, March 7, 1891, from this office to meet in New York City, for the examination of candidates for admission to the Medical Corps of the Army, etc. By direction of the Acting Secretary of War. Par. 6, S. O. 78, A. G. O., Washington, April 7, 1891.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine-Hospital Service, for the Three Weeks Ending April 7, 1891.

Surgeon Walter Wyman, to inspect Delaware Breakwater Quarantine Station. March 27, 1891.
Surgeon George Purpance, detailed as Chairman, Board of Examiners. April 1, 1891.
Surgeon H. W. Sawtelle, to proceed to Rockland, Me., on special duty. March 25, 1891.
Surgeon J. M. Gassaway, granted leave of absence for five days. April 1, 1891.
Surgeon John Godfrey, detailed as member Board of Examiners. April 3, 1891.
Surgeon Fairfax Irwin, detailed as recorder Board of Examiners. April 3, 1891.
P. A. Surgeon C. T. Peckham, granted leave of absence for ten days. March 26, 1891.
P. A. Surgeon Eugene Washin, granted leave of absence for thirty days. March 27, 1891.
1st Surgeon W. G. Stimpson, to proceed to Charleston, S. C., for temporary duty. March 27, 1891.

SPONTANEOUS UMBILICAL HÆMORRHAGE IN NEWLY-BORN INFANTS.

Read before the Medical Society of the District of Columbia,
February 4, 1891.

BY J. WESLEY BOVEE, M.D.,

VISITING PHYSICIAN TO WASHINGTON ASYLUM HOSPITAL; ATTENDING PHYSICIAN TO ST. ANN'S INFANT ASYLUM; AND OBSTETRICIAN TO COLUMBIA HOSPITAL FOR WOMEN AND LYNN-ING ASYLUM.

(Concluded from page 547.)

Diagnosis.—The diagnosis of this condition is usually not difficult. The appearance of blood on the dressings about the navel usually leads to examination of it and of the cord if still attached. The bleeding will be noticed in nearly every case. When it occurs from the end of the cord it may be mistaken for bleeding due to defective ligation. It may occur at various intervals and in small quantities, thus escaping detection. Especially will this be the case if the blood be very hæmæmic or if containing much bile. If the bleeding of this nature be from the end of the cord successive ligation will probably prove futile and the true nature of the malady will be recognized. There will be evidences of a constitutional affection, denoted by purpuric spots, hæmorrhage from other parts of the body, jaundice and other unmistakable symptoms.

Treatment.—The treatment of umbilical hæmorrhage in newly-born infants is of great importance, as about three-fourths of the cases succumb to it and those that withstand it usually are much weakened for some time afterward.

Occasionally cases have recovered with very little treatment, and others have resisted all forms of treatment for weeks and ended fatally. These slow persistent cases have allowed sufficient time for all the different remedies that could possibly be suggested, each and all failing to permanently check the hæmorrhage, or at least, not averting death. Successive ligation, applications of astringents of every kind, caustics, the actual cautery, collodion, plaster of Paris, acupuncture, transfixion with double ligature, ligation *en masse*, ligation by the puckering string method, ligation of the hypogastric arteries and umbilical vein by

Dakin's method and dissection about umbilicus with ligation of cord before its exit from the abdominal wall, have all been used in attempts to arrest omphalic bleeding in infants. Caustics and the actual cautery have done more harm than good, the bleeding usually beginning afresh as the slough comes away. The application of liquid plaster of Paris with proper ligation as first recommended by Churchill¹ is highly praised by Robinson² and others and was sufficient in one of the author's cases.

The ligation *en masse* is one of the most efficient topical remedies in use, but I think its benefit will be enhanced by the application over it of styptics and compression, or of plaster of Paris. Radford³ recommended cutting down and ligating the umbilical vein, and Dakin ligates the umbilical vein or arteries, first passing on a level with the lower edge of the umbilicus. He uses a hare-lip pin, passing it through the abdominal wall, under the arteries, and back through the abdominal wall. This pin he finds sufficient to control arterial hæmorrhage and for venous hæmorrhage he applies a figure 8 ligature over the ends of the pin including the umbilicus in it. This treatment is very ingenious and I think easily performed. It deserves further trial.

Dr. L. Elliot,⁴ of Washington, was I think, the first to adopt the suggestion of Radford and ligate the cord in the abdominal wall. He did not save his patient, but had the operation been done earlier, before the child was exhausted from loss of blood, and without anesthesia, I believe the result would have been better. Pout⁵, 1822, reported a case in which death occurred from bleeding from the left hypogastric artery and stated that in a similar case he would cut down upon the arteries and tie them. He, probably, deserves as much credit as does Radford for the early suggestion of the operation performed by Dr. Elliot. In nearly every case the treatment has been entirely local, with, perhaps, the addition of some cholagogue cathartic as calomel or sulphate of soda, when marked jaundice was present.

The profession has been slow to believe that

⁵ Linn's Lancet, 1822, p. 10.

this form of hæmorrhage was but a symptom of a general condition and have treated it locally instead of generally. The local treatment cannot be dispensed with but the internal administration of remedies to improve the condition of the blood and tissues in general is of great importance. The mineral acids, the muriated tincture of iron and tonics should be given. Brandy should be given to keep up the strength and in some cases ergot is admissible. The food should be the best, consisting principally of milk, and a building-up course instituted. If syphilis is present it must not be forgotten in the treatment. The general hygiene of the patient must be the very best. Prophylaxis might in a measure be carried out in the treatment of this trouble.

Dr. M. S. Perry²⁹ has treated mothers who have had children with hæmorrhagic diathesis in this way. He noticed women who were accustomed to take alkalies during pregnancy for dyspeptic or other symptoms were peculiarly liable to hæmorrhages after parturition. He accordingly gave mineral acids, instead, with good results.

It would be well to put mothers, during pregnancy, whose former children have had hæmorrhages shortly after birth, upon this treatment.

A CASE OF EXTRA-UTERINE RETRO-PERITONEAL PREGNANCY IN THE SEVENTH MONTH.

Read before the Chicago Gynecological Society, December 19, 1890.

BY W. W. JAGGARD, M.D..

PROFESSOR OF OBSTETRICS, CHICAGO MEDICAL COLLEGE, AND OBSTETRICIAN TO MERCY HOSPITAL, OF CHICAGO.

As my contribution to this evening's discussion, I beg to report a case of extra-uterine, retro-peritoneal pregnancy that is especially noteworthy on account of its clinical course, anatomy, diagnosis, and treatment.

History (Dr. Fitch C. E. Mattison).—Mrs. L. S., 36 years 6 months old, born in Altenberg, Saxony, coachman's wife; 5 feet 3 inches in height, 130 pounds in weight. Family history good; mother living, father died from septicæmia following injury to the hand.

Married two years ago (September 23, 1888). Date of commencement of last menstruation, April 15, 1890; first pregnancy. Course of early pregnancy distinctly abnormal; patient said she was in bed at least three days out of the seven from pain and weakness.

Dr. Fitch first saw the patient September 23, 9:30 A.M., when he found a woman, with a large abdominal tumor, in a condition closely bordering on collapse. She was cold, pallid, nearly pulseless, and vomited incessantly. Pulse 150, temperature 97° F.; relative suppression of urine (3 ounces non-albuminous urine by catheter). Mind clear; patient complained of difficulty in breathing rather than of positive pain. The patient and her friends informed Dr. Fitch that the alarming condition had developed gradually during the past three days, apparently in consequence of a day's washing. Dr. Fitch concluded that the abdominal tumor was the pregnant uterus. Upon vaginal examination he found the vaginal portion of the cervix uteri unchanged, and perceived no bleeding from the os. Upon the application of the usual remedies—dry heat and diffusible stimulants—the patient did not react.

At 4 P.M., I saw the case in consultation with Drs. F. E. Waxham, Bayard Holmes, and Fitch C. E. Mattison. The woman showed such ominous signs of considerable internal hæmorrhage and of severe shock that I thought death certain. Her mind, however, was clear, and Dr. Fitch informed us that her general condition was not more unfavorable than in the morning.

The fact of pregnancy was evident from the appearances of the mammae alone, without reference to the changes in the pelvic genitalia, or to the history of amenorrhœa in a woman previously healthy and perfectly regular. But the nature of the pregnancy and the cause of the bleeding were obscure.

Inspection revealed a single, symmetrical abdominal tumor as large as the gravid uterus at

the seventh month, with an arcuate fundus. Each horn extended upward to the lower border of the false ribs, while the median furrow dipped downward to a point four centimetres above the umbilicus. The size and shape of the tumor were suggestive of twin pregnancy. On palpation the walls of the tumor were so tense and unyielding that it was impossible to outline any contained object or to practice ballottement. Alternations in density—that is, intermittent uterine contractions—were notably absent. The tumor was absolutely flat on percussion. Maternal heart tones and pulsations of the aorta were transmitted with uncommon clearness and distinctness over all areas, but fetal heartbeats and uterine souffle could not be detected. Upon examination per vaginam it was evident, from the conical shape of the vaginal portion of the cervix uteri and from the persistent hymen, that the woman was a primipara. The vaginal portion of the cervix, three centimetres in length and unchanged, seemed relatively hard for such an advanced pregnancy; it was displaced to the right of the median line, and the os externum was closed. The vaginal vault, symmetrically convex downward, and apparently filled out by the head well engaged within the pelvic cavity, was directly continuous with the vaginal portion, and presented the sensation of equal resistance in all directions. Upon withdrawal of the finger it was found to be stained with blood, although there was no external hæmorrhage. The bladder contained one ounce of non-albuminous urine.

The diagnosis seemed to me to lie between intra uterine hæmorrhage from premature detachment of the normally implanted placenta, and hæmorrhage into the placenta of an extra-uterine pregnancy, with the weight of evidence in favor of the former view. Rupture of the normal uterus, or of the adventitious uterus of ectopic gestation, could be definitely excluded by reason of the single, symmetrical, perfectly circumscribed character of the tumor, and on account of the absence within the peritoneal cavity of fluid or unusual solid objects. In this opinion the other consultants concurred.

Any operative interference at this time was clearly contraindicated—first, because the woman appeared to be *in articulo mortis*; and, second, since the tumor had persisted of the same size at least since morning. There was nothing to be gained and very much to be lost by the immediate removal of such a mass of blood already extravasated. Accordingly, at Dr. Holmes' suggestion, we determined to transfuse and to await developments. Twenty ounces of the physiological salt solution (0.6 per cent.) were injected by means of Allen's surgical pump into the subcutaneous connective tissue about the inferior angles of the scapulae and over the lumbar region. The insertion of the needle caused little

pain, and the injection of the solution and its dispersion by rubbing only slight discomfort. About one-half hour was occupied in the act of transfusion, and at the end of this period no apparent effect on the circulation was observed. Dr. Holmes thought there was an increase in the volume of the pulse, but I was unable to perceive any change. Dry heat to the body was continued, and rectal alimentation (six ounces of peptonized milk every eight hours) was recommended.

Then we left the patient in the care of Dr. Fitch, with the understanding that in the event of death we should be summoned to the autopsy, or, in case of sufficient reaction, to the woman's active relief. 10:30 P.M.: Pulse 150, temperature 97° F.

Second day, September 24, 7 A.M.: Pulse 130, temperature 100 $\frac{2}{3}$ ° F.; 2 ounces of urine by catheter that contained neither sugar nor albumen. The woman rose from her bed without aid and walked across the floor. 10:30 A.M.: Consultation. Improvement was marked, in consequence of, or independent of, the transfusion and rectal enemata. No apparent change in the abdominal tumor nor in the vaginal portion of the cervix uteri; slight oozing of blood from the os externum. Upon careful and prolonged physical examination of the abdomen no additional facts were discovered. The woman was still too feeble to bear a severe operation; she had plainly gained during the night; moreover, the case looked more and more like an example of accidental hæmorrhage, so we determined to wait. Enemata of peptonized milk, and ammonium carbonate per os, since the vomiting had ceased, were recommended.

10 P.M.: Pulse 120, temperature 99° F. Patient complained of pain in the region of the abdominal tumor, but no contractions were perceptible and no effect upon the vaginal portion of the cervix was apparent. Morphine hypodermatically.

Third day, September 25, 7 A.M.: Pulse 100, temperature 99 $\frac{2}{3}$ ° F.; 2 ounces of urine by catheter that contained neither sugar nor albumen. 10:30 A.M., consultation. General condition much better than at any time since we saw the case. No change in the abdominal tumor nor in the vaginal portion. Again, for the third time, we discussed at length the propriety of exploratory dilatation of the cervix and of exploratory laparotomy, but, in view of the apparent nature of the case and of the distinct and progressive gain, we decided to wait. We left the case in Dr. Fitch's care, with the understanding that we should be called in the event of any change for the worse. 9:30 P.M.: Pulse 98, temperature 99 $\frac{2}{3}$ ° F. Voided voluntarily 6 ounces urine since previous night.

Fourth day, September 26: Pulse 100, temperature 99°. Voided 8 ounces urine, passed a

comfortable night, moved about in bed, and sat up in a chair while the mother made the bed. Drank with relish large quantities of peptonized milk. No change in the abdominal tumor nor in the vaginal portion of the cervix.

9 P.M.: Pulse 100, temperature normal; urine, 10 ounces since morning.

Fifth day, September 27, 8 A.M.: Pulse 96, temperature normal; 20 ounces of urine. Patient passed a comfortable night, but complained of some pain in the back and in the region of the lower abdomen. No change in the abdominal tumor nor in the vaginal portion of the cervix.

9 P.M.: Pulse 100, temperature normal; 36 ounces of urine.

Sixth day, September 28, 8 A.M.: Pulse 96, temperature 99 $\frac{2}{3}$ ° F.; 26 ounces of urine. Patient passed an uneasy night, restless, and complained of pain. Slight bowel movement. One teaspoonful and one half of compound licorice powder was followed by five free discharges of fluid feces; complained of considerable abdominal pain. No local change. 9 P.M.: Pulse 120, temperature 101° F.; 40 ounces of urine; slight discharge of blood per vaginam.

Seventh day, September 29, 8 A.M.: Pulse 112, temperature 101° F.; 20 ounces of urine. Bowels moved four times during the night, with pain, and the discharge of large quantities of fecal matter. No local change.

9 P.M.: Pulse 120, temperature 102° F.; bowels moved four times since morning, but pain slight.

Eighth day, September 30, 8 A.M.: Pulse 104, temperature 101 $\frac{1}{2}$ ° F.; great pain.

9 P.M.: Pulse 114, temp. 103 $\frac{2}{3}$ ° F.; great pain.

Ninth day, October 1, 8 A.M.: Pulse 116, temperature 102 $\frac{2}{3}$ ° F. Passed a comfortable night. Rigor at 7:30 A.M.

10:30 A.M.: Consultation. I saw the case for the fourth time with Drs. Waxham, Holmes and Fitch. Marked changes had occurred in the abdominal tumor. It had increased slightly in size and was notably emphysematous; on percussion the sound, while not absolutely flat, was still not resonant, as in physometra. Even on this occasion it was impossible to outline the body of the fetus. Vaginal portion of the cervix uteri absolutely unchanged; slight oozing of blood from the os externum.

Plainly the woman was the subject of septic infection that had its origin in the abdominal tumor, and the indication for active treatment seemed absolute. We discussed exploratory abdominal section and exploratory dilatation of the cervix, and decided in favor of the latter. The patient's critical condition was fully recognized, and her friends were informed of the possibility of death during the operation.

Operation 11 A.M. Ether narcosis. Patient placed on a table, and with all antiseptic precautions, I dilated what I supposed to be the cervix

uteri by means of Hegar's bougies and Robert Barnes' water bags. Upon the introduction, without violence, of a Hegar bougie No. 6 through the os externum, a free discharge of liquor amnii stained with blood occurred. Uncommon difficulty was encountered in the use of Barnes' bags. Finally, however, with Dr. Waxham's aid, I succeeded in passing two fingers into what I thought was the cavum uteri, recognized the foetal head, with the occiput to the right and posterior, O. D. P. Failing to turn by the method of Braxton Hicks, the canal was further dilated, the right hand introduced, and version by the feet with immediate extraction easily accomplished. The child, male, was dead and macerated, its tissues emphysematous. The placenta, detached for one-half, was found to be firmly adherent for the rest of its area to the site over the right antero-lateral wall of the cavity. Several bands of dense connective tissue were sawed through by the hand, and the after-birth delivered. During version I felt the promontory of the sacrum and the pulsation of the aorta with alarming distinctness; but it was only after delivery of the placenta that I recognized the fact of extra-uterine pregnancy. At this time I felt the posterior surface of the normal uterus, heretofore covered in part by the placenta.

The woman was put to bed and dry heat applied; death followed in a few moments. The duration of the operation was one and one-fourth hours; the total quantity of blood lost slight. I attribute death immediately to the combined effect of trauma and ether.

Autopsy.—A limited post-mortem examination was permitted and at once performed. Peritoneal cavity dry, free from blood; a few adhesion bands, evidently old, stretched between adjacent coils of small intestine, but the structures were not matted together in any important degree. The mesentery, unfolded, and the small intestines greatly separated by the unfolding of the mesentery, together with the unfolded right broad ligament and the normal uterus, constituted the anterior covering or wall of a large sac that extended from the pelvic floor below to the transverse mesocolon above. The thickness of this anterior wall was not much greater than that of the mesentery and flattened-out small intestine, except in the region of the placental site—the under surface of the right broad ligament and the upper posterior surface of the uterus. Here the wall was one centimetre in thickness, and contained a broad stratum of non-striated muscular fibre, the only visible sign of an adventitious uterus. Upon the removal of the anterior covering the posterior wall was found to be the usual undifferentiated sub-peritoneal connective tissue.

The cavity thus bounded was chiefly abdominal, to a lesser degree pelvic. It was extra-uterine and retro-peritoneal. In addition to old blood

clots and fragments of the foetal envelopes, the cavity contained several lumps of maternal faeces; two perforations through the inferior border of the small intestine were discovered, probably due to pressure atrophy.

The uterus, slightly deflected to the right of the median line, enlarged to a degree corresponding to the tenth week of pregnancy, presented the following measurements: Length, equally distributed between corpus and cervix, 10 cm.; thickness of the wall of the corpus, 2.5 cm.; of vaginal cervix, 1 cm. The uterus was situated directly in front of the child's head. Examination showed that the lower mouth of the canal, through which the foetus had been delivered, consisted in the os externum, while the mouth communicating with the sac was a rupture through the posterior wall of the lower uterine segment, at a point where the tissue was as thin as blotting paper. In other words, I had passed the bougie per os externum through the posterior wall of the supravaginal portion, thinned out from pressure atrophy. The decidua vera, partly detached, had not been extruded from the cavum uteri.

The left ovary and Fallopian tube were apparently normal; the tube was pervious; no corpus luteum. The right ovary and tube were completely lost in the gestation sac.

The placenta, pretty well disintegrated by the force of the original hæmorrhage and by subsequent changes, showed a few white infarcts and several bands of tough connective tissue that firmly bound the organ to its site over a considerable area. The after-birth was also studded with old coagula. Fragments of chorion and amnion were visible, attached to the placental edges. The foetus, male, well developed, macerated, 1,165 gm. in weight, 40 cm. in length, corresponded to the seventh month of pregnancy.

The items in the history of this melancholy case that I beg to call particular attention to are:

1. This case presents a typical example of the classical picture of extra-uterine pregnancy, in that the anomaly occurred in the person of an old primipara that had been married for some time before the event of pregnancy. It is true, the right tube and ovary were involved, instead of the same organs on the left side; but then the dissection of specimens collected within recent years shows that the election of the left side is not of such relatively frequent occurrence as was formerly believed to be the case.

2. The anatomical findings indicate that the pregnancy, originally tubal or ovarian, developed in the cavity of the right broad ligament. Later the ovum passed up into the abdomen, lifting up the peritoneum and unfolding the mesentery, still maintaining its extraperitoneal character. Death of the foetus, from hæmorrhage into the placenta, probably occurred about the time and in conse-

quence of the day's washing, already mentioned. The bleeding, however, took place within a closed sac, and the hæmorrhage ceased when the pressure of the extravasated blood became equal to the general blood tension of the mother. Infection doubtless resulted from perforation of the small intestine, although, of course, other modalities are possible.

It is of interest to note that the cervix persisted in its original virginal length. That is to say, the anatomical os internum was situated midway between os externum and fundus, in a uterus hypertrophied under the influence of extra-uterine pregnancy to a degree corresponding to the tenth week. In pregnant uteri of the same date, the cervix is both relatively and absolutely shorter. (Compare Braum, "Der männlich und weibliche Körper in Sagittalschnitt," Leipzig, 1872; Bencikser, "Beiträge zur Anatomie des schwangeren Uterus," Stuttgart, 1887, Taf. i.). Does not this fact seem to indicate that during pregnancy the supravaginal portion of the cervix uteri is dilated from above downward, or, in other words, that the lower uterine segment is derived, in part at least, from the cervix?

3. As regards *diagnosis*, all the medical men connected with the case must feel some degree of chagrin over the failure to locate exactly the pregnancy.

Still, the fact that four medical men, not without experience in this class of cases, and presumably qualified, deliberately, and independently of each other, formed the same opinion, though an erroneous one—this fact indicates that the case presented extraordinary difficulty. Possibly, also, this fact may add to the instructive value of this communication. Furthermore, the circumstances under which we saw the case were unfavorable to an accurate diagnosis. We first saw the woman in a state closely bordering on collapse, and her precarious condition at a later period seemed to contra-indicate the exposure and fatigue incident to a more thorough examination. Then, too, an account of the character of the abdominal tumor already mentioned, we were utterly unable to elicit, by the usual method of physical exploration, sufficient signs to constitute a positive diagnosis. During the course of the case, however, there were presented certain significant signs that deserved clearer recognition and more exact valuation. Some of these significant signs were:

1. The abdominal tumor was absolutely quiescent throughout the period of observation. The woman, indeed, at times complained greatly of abdominal pain, but this symptom was not attended by rhythmical contractions, with their characteristic changes in the contour and consistency of the tumor. In the severest cases of "accidental hæmorrhage" some sign of uterine contractions is almost always manifested within

twenty-four or forty-eight hours after the occurrence of the accident.

2. The maternal heart tones were transmitted uncommonly clearly and distinctly over all areas of the tumor, and the uterine souffle was absent.

3. The vaginal portion of the cervix uteri persisted relatively hard and unchanged in length throughout the eight days of observation. Every one is familiar with Goodell's off-hand rule: "When the cervix is as soft as one's lips, the woman is probably pregnant; when it is as hard as the tip of one's nose, the womb is most likely empty." In this case the vaginal portion was softened, yet not to the degree commonly observed at the seventh month. The persistence in the length of the vaginal portion—absence of effacement and dilatation—was still more significant. In all these cases of "accidental hæmorrhage" that I have observed, marked changes in the vaginal portion appeared and progressed within the first twenty-four hours after the accident.

4. The vaginal portion of the cervix was distinctly deflected to the right of the median line.

The evidence accumulated from these four signs, although negative in character, was still of a degree to overbalance the evidence in favor of "accidental hæmorrhage," which, as before remarked, consisted in the fact of advanced pregnancy, of the single, symmetrical form of the tumor, of the apparent direct continuity of the abdominal and pelvic tumor, of the vault of the vagina convex downward and filled out by the head. At least the negative evidence ought to have deterred from a therapy based upon an absolutely positive and exclusive diagnosis.

The fact that the hæmorrhage through the os externum was an insignificant oozing might be interpreted as equally in favor of both "accidental hæmorrhage" and extra-uterine pregnancy. I have encountered examples of the former anomaly in which scarcely a drop of blood escaped into the vagina.

Finally, an exploration per rectum was not made. Such an examination, I believe, might have revealed the real nature of the case.

4. Under the topic of *treatment* I wish to mention: 1. The apparently important effect of the subcutaneous injection of the physiological salt solution. The total quantity injected—twenty ounces—was absorbed without local reaction within twelve hours after the operation. At the same time, however, peptonized milk was exhibited per rectum. 2. Two procedures were discussed when we first saw the woman and at each subsequent meeting. These were, in view of the uncertain diagnosis, exploratory abdominal section and exploratory dilatation of the cervix uteri. In the light of the autopsy, laparotomy would have accomplished nothing except to reveal the nature of the case, because the small intestine was so generally distributed over the an-

terior wall of the sac, because the product of conception was retroperitoneal, and because the retroperitoneal connective tissue had been extensively dissected up in all directions. It would not have been possible even to ligature, on the peritoneal side, the uterine, ovarian, and spermatic arteries before their distribution to the placenta, for the reason that the relations of these vessels were so distorted that they were not found after prolonged search during the autopsy. Exploration through the cervix, therefore, was indicated, and it was only unskilful or unfortunate use of the sound that led to the serious mistake in the operation. Under the conditions of the case, the vaginal operation for advanced extra-uterine pregnancy would have been the operation of election, even in the presence of the risk of bleeding from the placental site.

It may be urged, in criticism of the management of this case, that the golden opportunity for operation was presented and lost, when the patient had recovered in some degree from shock and hæmorrhage, but had not yet become infected. In reply to this, I desire to say that while the actual time of the operation was unfavorable, still it was the only time we were summoned to the case when the indication for interference was absolute. As a matter of fact, I believed the woman received a necessarily fatal injury when the original hæmorrhage into the placenta occurred, and when the retroperitoneal connective tissue was so extensively destroyed.

2330 Indiana Ave., December 19, 1890.

TREATMENT OF GALLSTONES.

Read before the New York State Medical Society, February, 1891.

BY WILLIAM WOTKYNs SEYMOUR, A.B. (Yale),
M.D. (Harvard);

OF TROY, N. Y.

FORMERLY HOUSE-SURGEON OF THE BOSTON CITY HOSPITAL; MEMBER OF THE AMERICAN AND BRITISH MEDICAL ASSOCIATIONS; FELLOW OF THE N. Y. STATE MEDICAL ASSOCIATION AND OF THE AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNÆCOLOGISTS; PROFESSOR OF THE SURGICAL DISEASES OF WOMEN IN THE UNIVERSITY OF VERMONT.

In considering the treatment of gallstones we have to consider the treatment during the paroxysm, during the intervals between the paroxysms, medical and surgical measures for their radical relief and the constitutional vice leading to their formation. During the paroxysms I do not think anything superior to hypodermatic injections of morphine and atropine. They are capable of very accurate dosage, but must be very carefully employed, for some patients are extremely susceptible to these drugs and one who has long had the drugs only with benefit may suddenly be thrown into a very alarming condition by the usual dose. I should in an adult prefer to administer repeated doses of a $\frac{1}{4}$ grain of morphine and a 1-150 grain of atropine, than to

give as some do at the very outset $\frac{1}{2}$, 3-4, or even a grain of morphine. To the hypodermics, chloroform or ether by inhalation are the only possible rivals, with the added disadvantage that in employing the anesthetics, we expose the patient to the dangers of anesthetization.

My friend Dr. James Hutchison, of Troy, not infrequently has employed chloroform hypodermatically as an adjuvant to the administration of morphine and atropine, and has found it of excellent service. He first injects a half drachm of pure chloroform, and follows it by an injection of morphine and atropine. The chloroform acts almost instantly in relieving the pain and its influence persists until the morphine and atropine begin to exert their influence.

With morphine alone I have never had such prompt results as with a combination of it and atropine. The atropine, by relaxing the muscular fibers of the gall-bladder, and of the abdominal muscles, puts in abeyance one of the most potent factors of gallstone colic. The present formula I use is Magendie's solution with half grain of sulphate of atropia to the ounce. Formerly I used a grain of atropine, but I found the amount of atropine altogether too large; giving rise, in some cases, to paresis of bladder lasting for several days, hallucinations of sight, together with dryness of the throat that was most tormenting. If the agonies did not yield promptly to hypodermatics of morphine and atropine I would certainly have recourse to chloroform or ether by inhalation, personally I would prefer chloroform, especially if it be administered, as it ought, by the physician. Not merely do morphine and atropine, as well as the anesthetics, relieve the pain, but they produce such relaxation of the tissues involved that the expulsion of calculi is greatly favored. Whether prolonged anesthetization and the consequent saturation of the tissues with them can have any actual solvent power on calculi, I think very improbable, although some practitioners are inclined so to believe, as a result of their trials in some severe cases. If from any reason we can not employ drugs hypodermatically, they may be administered by the rectum in shape of enemata or suppository, by the mouth, or has very recently been suggested, in the case of morphine, by insufflation into the nose. As a rule, vomiting precludes giving medicines by the mouth, and we are consequently limited to the rectal, nasal or epidermal methods, and for these methods, morphine and atropine or the various preparations of opium and belladonna are the main stays. Hot baths during the paroxysms are of great service.

From the fluid extract of wild yam (*Dioscorea Villosa*) I have had very good results in some cases. The relief from pain has been very prompt at times, but it has the disadvantage of being only administered by the mouth and its vile taste

is very difficult to conceal. As to chloroform, ether and turpentine by the mouth, alone or in their various much lauded combinations, I have met with few stomachs which could bear them, and where they were borne, I have seen no benefit which could not be sooner attained by morphia and atropine. As to their solvent action, more will be said anon. Large doses of olive oil have some effect, as has been shown in recent experiments in increasing the flow of bile, but its reputation for expelling enormous numbers of calculi depends upon masses of saponified oil being mistaken for gallstones. Harley, however, is inclined to believe that oil removes what he terms sleatomatous concretions.

In the case of a person who is subject to these attacks it is, I think, desirable to advise their always having about them some preparation of opium in case they are attacked on a railway journey or anywhere where immediate assistance is uncertain. Any one who has endured the tortures of an attack when assistance was not to be had will appreciate the sense of security thus given. The vomiting is often one of the most harassing features of these cases and the twisting contractions of the empty stomach, multiply manifold the agonies of the extrusion of the stone. In such circumstances it is good practice to keep filling the stomach with warm water so that it may have something to contract upon. The relief from this simple procedure is most welcome, as any who have been "through the mill" can testify.

After the termination of a paroxysm we are confronted with the question of treatment to eradicate the disease. For an understanding of the indications we must bear clearly in mind the constitution of the calculi, the location in which they are formed and the conditions favoring their formation. The calculi consist almost entirely of cholestone in combination with salts and biliary coloring matter in various proportions. They occur at every period of life, although more common after thirty years, and have even been found in the fetus, and have been found every where in the biliary canals, from the liver to the duodenum. That gallstones are not formed in the gall-bladder alone seems to be very generally overlooked, and hence has arisen the illogical advocacy of some surgical procedures as methods of election. Normal bile is thin and alkaline or neutral in its reaction, and whatever favors its becoming thicker or acid favors the precipitation from out of it the cholesterine nominally present. Probably the most common cause is catarrhal affections of the bile ducts and gall-bladder which are in two ways favorable to the formation of calculi, the first by the formation of mucus which splits up the unstable bile salts, and, second, by the obstruction arising from catarrhal swelling checking the flow of bile, favoring the reabsorption of its watery

elements and the precipitation of the cholesterine held in solution. A dietary rich in fats, a sedentary life with full diet, and paludal poisoning seem to favor the formation of gallstones. Hence we should interdict fats and sugar, encourage exercise and combat every malarial taint.

Although ether, turpentine, and chloroform have long had a reputation in gallstone cases and many have claimed for them, especially in the well known Durande Mixture, a true solvent action on the stones, the evidence is that not only do they have no such action, but that even if the stomach can bear them they do not in my experience and that of my friends of whom I have inquired, relieve the pain. Buckler *Boston Med. and Surg. Journal*, October, 1876, claimed that 5ss doses of chloroform every four hours combined with the saccharated succinate of iron 5 t.d. would actually dissolve calculi in the gall-bladder. But while benefit has undoubtedly followed the administration of these drugs, especially of the succinate of iron, I think it is unproven as yet that they have actually dissolved or eroded stones. Even in a test-tube containing several volumes of chloroform I have failed to dissolve cholestone stones of less than 6 grains in five hours. The cholate of soda recommended by Schiff and Dabney occupies a somewhat different position, although its solvent action is not proved, yet it supplies to the blood a salt in such form as to be very favorable to the maintenance of the alkalinity of the bile and the retention in solution of the cholesterine. However, it is from the salts of soda or to the vegetable acids that by common consent we are to expect the best results, if not in dissolving, at least in preventing the formation of calculi. Although Harley thinks that with the alkalis one can as surely dissolve calculi as when in a test tube, it does not seem rational, and proof is certainly wanting of their solvent action. However there can be but little doubt that they are very efficient in removing the catarrhal conditions of the biliary canals and in maintaining the solubility of the cholesterine.

Harley prefers the sulphate and bicarbonate of soda. Bartholow the phosphate of soda. In my own cases I have especially used phosphate and salicylate of soda with excellent results; not, I am free to admit, with any hope of dissolving stones already formed, but with the hope of correcting the conditions favoring their formation. With these salts I have not infrequently employed the wild yam and Carlsbad salts and iron, and have frequently been pleased with the long immunity from attacks and the improved condition of health. From what I have already said it may easily seem that I do not believe gallstones are ever dissolved in the body. Patients may remain years without an attack in apparent

health and like the late Dr. Sabin, of West Troy, may credit daily doses of bicarbonate of soda with removing the stones and curing the disease, and yet years later have sudden fatal attacks, as in Dr. Sabin's own case, and a gall bladder filled with stones. For some years I have inquired of my professional acquaintances how many fatal cases of gallstones they have seen, and very large though the number has been, it does not in my opinion represent a third of the direct mortality, and when the secondary effects are considered, chronic diseases of the liver, cancer, etc., recurrent gallstone attacks must answer for a very large mortality.

My belief is that in all cases where the attacks recur with frequency and severity in spite of a moderately prolonged treatment with the alkalis, iron and wild yam, operation is the only wise course to pursue. But I mean operation not as a forlorn hope, but before the powers are broken by incessant, agonizing pain, impaired digestion, or cholæmia. In ordinary cases operation will not be difficult, but in neglected cases, cases with repeated attacks of local peritonitis, with prolonged jaundice and large impacted stone, the operation may try severely the most accomplished surgeon, and the mortality instead of being 5 per cent. may amount to 25 or 30 per cent.

It is not fair to decry the results of surgery in these cases when months have been allowed to pass by during which the patient has been racked with pain, weakened by impaired digestion, or so poisoned by prolonged retention of bile that all the vital organs, especially the heart, are at their lowest. What the profession at large must learn and must teach, is that in early operation in the hands of expert abdominal surgeons, the mortality is as low as, or even lower than, in ovariectomy. The sentiment of the profession ought soon to become such that the man who in a case of intense jaundice from impacted stone or repeated attacks of colic allows a patient to go months without surgical relief will be regarded as culpable as he who waits until stercoraceous vomiting has occurred in strangulated hernia before advocating operation. It has been my fortune to see several cases in which even eminent medical men have "monkeyed" week after week with such cases, and have decreed operation as unjustifiable because of the presence of a supposititious cancer, until after months of suffering the patients have either temporarily recovered or died from gallstone accident, and no cancer has been found. Certainly a careful exploratory incision, even in such cases, can do no harm, and the patient ought to be given an early opportunity to have the doubt settled, when, if ever, operation will avail.

Now as to the methods of operation, we can limit ourselves to two, both of which are now not rarely done; cholecystotomy or incision of the gall-

bladder, and cholecystectomy or excision of the gall-bladder. Although favored by such brilliant surgeons as Sir Spencer Wells (Bradshaw Lecture, 1890), by Kocher, of Bern, and others, I can but regard excision of the gall-bladder as a thoroughly irrational procedure when done as an operation of election. It starts with the unwarranted assumption that the gall-bladder is the only organ in which gallstones are formed and that with its removal the *fons et origo Mali* is removed. Were gallstones formed in the gall-bladder *alone* there would be little justification for the removal of the organ; save if it could be shown that the mortality of excision was better than that of cholecystotomy. But in addition to the fact that the gall-bladder probably has some physiological office besides being a receptacle for bile the results had from excision are very much worse than from incision, drainage and suture of the organ to the abdominal walls. In cases of hæmorrhage, contracted gall-bladder, or where all the tissues are matted together, we may be driven to removing the organ, but as an operation of election it ought never to be entertained. On the other hand, cholecystotomy with suture of the gall-bladder to the abdominal wall after opening and evacuating the gall-bladder, permits the excision or crushing of stones in the common duct and affords an outlet to the bile, until any inflammatory or traumatic swelling of the ducts has subsided. Furthermore, if a stone in the common duct has been overlooked, by establishing a biliary fistula the cholæmia is relieved and one can later attack the impacted stone. If, however, a stone impacted in the common duct is overlooked when the gall-bladder is removed, one of two things must speedily ensue, either a forcing of the ligatured cystic duct by the retained bile and consequent fatal peritonitis, or fatal cholæmia.

The objections to suturing the gall-bladder and dropping it back into the belly are, that it exposes the patient to the risk of the sutures being forced by retained bile, especially if a stone in the common duct has been overlooked, and the mortality of this operation has justified the theoretical objections. To doing the operation in two stages, first suturing the gall-bladder to the abdominal wound and opening it later when adhesions have formed, the objection is that immediate incision with suture to the wound has proved reliable and consequently the double-timed operation is unnecessary.

The objection to cholecystotomy that a fistula sometimes remains is of little consequence in view of the enormous advantage it offers over the several operations, and obstinate fistula occur most commonly where stones in the common duct have been overlooked. But even this rare sequence has been cured by both Grig Smith and Winifarter through cholecysto-enterostomy; that is in uniting the gall-bladder to the intestine and

subsequently closing the external opening. The attachment of the gall-bladder to the abdominal wall gives rise to no discomfort after a few weeks, and during the first few weeks it is very slight. In my own case I have fenced, sparred, swum and rowed without the slightest discomfort and without harm.

In a paper read before the American Association of Obstetricians and Gynecologists, in September, 1890 (New York *Medical Record*), I advocated as a result of an observation in one of my own cases, the attempt, in cases of contracted or friable gall bladder, instead of extirpation of the organ, to make out of the omentum an artificial sac and to stitch it into the abdominal walls, with drainage. Very pleased was I subsequently to learn that this had already been successfully put in operation by Mayo Robson.

My conclusions are:

1. That it is as hopeless to expect to dissolve gallstones as to dissolve stone in the bladder.

2. Protracted medical treatment should give way to operative measures in face of increasing frequency and severity of attacks.

3. Operation should be done early and not delayed until a forlorn hope.

4. Better a late operation than none at all where death is otherwise inevitable.

5. Cholecystotomy should be the operation of election, cholecystectomy never.

6. The mortality in the hands of expert abdominal surgeons is very small, probably less than 5 per cent.

7. In doubtful cases exploratory incision ought to be much more frequent, especially as the risk is infinitely less than the probable benefit.

8. A post-mortem diagnosis is no help to the patient, and but little satisfaction to the friends.

My views may seem dogmatic to many, but they are the result of the observation of many cases, of the disasters of dawdling, and of much reflection over my own operations, and especially the daily weighing of the merits of operative measures when my own life was in the balance, and the ever present apprehension and unutterable torture led me to accept for myself the operation which has given me the health and strength which I now enjoy.

THE TENTH INTERNATIONAL CONGRESS AT BERLIN, AS I SAW IT.

Read before the Kings County Medical Association, March 10, 1891.

BY E. J. CHAPIN MINARD, M.D.,
OF BROOKLYN, N. Y.

I saw the capital city of Imperial Germany in the early morning from an elevated railroad depot, on Friedrich-Strasse. After having washed the dust from my eyes, and given twenty-five cents for so doing, I took a look at my strange surroundings.

To see this city had been a dream of childhood. The roofs decorated with statuary and symbols, the clean asphalt pavement, the peculiar architecture of the buildings, the silent way of doing the city work, and the subdued, even tread of companies of soldiers going to morning parade, keenly excited my curiosity. I was satisfied even to look over the city which held the greatest ruler and the grandest man—Virchow—the father of cellular pathology.

The unexpected greetings of long ago friends, known as college chums, and the reminiscences of college life, made me feel kindly towards the whole German nation and at home at once. The friendly reception of the Secretary, Dr. Lassar, the acceptance of credentials as delegate, the presentation of the queer little badge, the assignment to the Gynecological Section, without fuss or blunder, were very agreeable.

The building in the Ausstellungen Park was the place assigned to the Sections of the Congress. It was noisy and close, there being no corridors, and much glass and skylight. The three general sessions of the Congress were held in the Circus-ring. It reminded me of the descriptions of a Roman amphitheatre, when Rome was in her glory. It was bright and gay with light and color. Its magnificence was enhanced by the presence of army officers and surgeons, who wore imperial decorations upon their gay uniforms, which were marks of fidelity in the service of a worshiped Emperor. Others wore badges sparkling with jewels, for work done in laboratories and societies. These gay trappings seemed a fitting framework for the eight or ten thousand scientists and scholars from all parts of the globe, who had come to submit to a tribunal of the noblest criticism, the results of their truest thoughts and most patient labors. It was an event to enrich a lifetime.

To hear and see Virchow, who, crowned with the knowledge of three-quarters of a century of research, has lived to verify and rectify his own investigations, and whom his countrymen have honored, idolized and *outgrown*, but who to-day, in his waning life, is the one scientist who can measure arms with the younger giant, Koch; to touch the hand of Apostoli, and hear him defend "galvanism" as only a master can; to return the smile of recognition on the broad, good-natured face of Martin; to look with reverence approaching awe upon the faces of Koch, Pasteur, Lister, Esmarch, Tait, Billroth, Oppenheim, Sir Spencer Wells, and a host of others, with more or less unpronounceable names; to find Lusk, Parvin, Senn, Wood, Billings and many others of my countrymen in their midst; to hear ten tongues and twice as many dialects spoken, yet to understand the universal language of science, and to be an accepted member of this great body of investigators and thinkers—is an honor to be

worn with fidelity that only those who wear the motto, "*Guard the Faith*," can fully understand.

Mexico met Russia; Great Britain met Italy; Spain met Japan; Holland and Sweden met Asia and the Islands of the Sea; France, shy and sullen, met Germany, and grew cheerful under the kindly greetings; and America, with her 657 delegates, had no favors to ask, nor had she need to blush for lack of talent.

But the extreme modesty which marked the demeanor of Americans was not pleasing. Perhaps our national nervousness develops self-consciousness—or is it a lack of university training?

Our papers were fine, and some led in the departments to which they were assigned. Brooklyn had her place. Dr. French led in his specialty—the throat. His paper was *sui generis*, as you all know. Dr. Parvin's paper equalled anything in its line; and Dr. Wood's address on "Anesthetics" was a State paper, and was assigned a place of honor—that of the closing session.

To give an idea of the subject-matter of even a few papers is impossible. The most advanced ideas were treated respectfully and discussed fairly. Apostoli was hissed a little; but as it came from the French, we all smiled and applauded louder.

The whole line of antiseptic treatment culminated in one word—"cleanliness." There were new instruments, which Americans bought to bring home and improve upon. We are ahead in the use of the drugs (the new remedies) which bear the German trademark.

While listening to the papers of these intellectual giants, one could divine that a great tidal wave in science was imminent—and that it centered upon the discovery of Koch.

Every delegate will remember so long as reason remains, the scene when Koch stepped forward to read his "Researches." His deep-set eyes, so true and steady; his gentle, yet decided bearing, said so plainly that he was giving us the "truth" as he had found it; and scientists accepted it without question. When the greetings had subsided, it was far more interesting to watch the faces of the listeners than to follow his reading with the dull ear of my American German. The lines and shadows on the faces of those listeners from the ends of civilization quivered like the needle of the milliamperemeter, when the current is near. I have heard from forum and pulpit passionate orations, which have made my countrymen famous throughout the world; but this man who stood here giving to dying humanity a respite, would have been made a god in the days of Greece.

The social resources for festivities which a gay capital city has at its command were called into play, and the delegates were wine and dined and amused to satiety. The banquet at Kroll's Garden—"the good-bye feast"—"a hotel on a pic-

nic excursion," were things undescrivable to an American. How from ten to fifteen thousand people were fed and wine without fee, and how each coterie and table mixed without mingling, is incomprehensible.

Some one has said, "To learn at the fountain head of the masters, and to love historic Germany, is only scholarly."

We have all the facilities in our great cities for scientific investigations, except, perhaps, the deplorable class to practice upon—and may that never exist!—but we work too fast and are not yet painstaking enough. Few of us so far have had the patience to work up clinical material.

But the woman's side of this tidal wave of medical science may not be ignored. The furore with which Germany has received Koch's investigations, compared with the reception of Jenner's mighty discovery, points to the growth that has taken place in this great Empire in ten decades, and is suggestive.

When the Congress was younger and smaller than it is to day, it met in Amsterdam. A woman physician of unusual ability was put upon the programme with a paper on pathological studies made in Syria. Objections were made to her and her paper; but parliamentary rules were stronger than German barbaric usages, and she read. In august executive session this Congress voted that no woman should be admitted into its ranks so long as Germans held control. The Congress grew in knowledge and in numbers, and met now in one country, now in another, till it reached London. Titled and diplomaed ladies sought admission to it, now that Germans did not control. Surely their Queen would decide in their favor! but the Empress of India said, No! American women smiled, "for are we not all princesses in America?"—and turned their attention to work, fully believing in the "survival of the fittest."

The Congress grew, till it covered the whole earth, and came to Washington. Americans surprised it and taught it to respect Western medical work. Women physicians had become so absorbed in the work of "surviving" that it was entirely forgotten. A few captured the giants from abroad, taking them to our hospitals to show them our working material.

The re-instatement of woman in medicine has not yet exceeded a half century. This re-instatement began in New York, and was re-inforced by Berlin. England and Germany have the honor of the nationality of the first two regularly diplomaed women doctors in the world. One graduated from the College of Geneva, N. Y., the other from Cleveland, O. But only in America could this have been done; and only women from the Old World, well grounded in literature and midwifery, could have laid such a foundation as to-day underlies the structure of woman's education in medicine.

The result of her work has been to increase our number from eight to thousands within the past twenty-five years; to build two medical colleges equal to the best male colleges; and to graduate doctors with as high a degree of scholarship and preparation for work as male colleges have done, with a hundred years of experience, and a thousand of culture. There are now forty-seven colleges to which women are admitted in the United States and Canada, fifteen of which have been built for her alone.

Women doctors in America had now become sure of surviving, and when at last the Congress decided to hold its tenth triennial meeting in Berlin, they were reasonably sure of being fellow-shipped. One thing an American will not brook without resenting—that is being snubbed—so great caution was observed among a few, and quietly every line sent out from the executive committee at Berlin was scanned with great care. When a male delegate was asked how he thought Americans would be received he said, "They will be snubbed, of course; the German knows he has it all his own way." The result proved otherwise. Americans were honored as much as they deserved. If there were individual heart-burns it must have been from lack of knowledge of local customs, or of the language. As for woman—without premeditated effort there were more than twenty women in these sessions. There were chemists, biologists, physiologists, botanists, dentists, and among these were fourteen women physicians, one being an honored delegate from the New York State Medical Association, and admitted as such.

Germany is now the only civilized Government where women are not allowed to practice medicine as physicians. Women here obtain their diplomas, usually, from Zürich, and are admitted to all the rights of midwives (which are many), but are not allowed to use the forceps, write a death certificate, or one of vaccination.

The admission of women delegates to this Congress in the face of the decisions of former sessions, was hailed with enthusiasm by the women of Berlin. "How did you do it? You do more in America in twenty years than we do here in a hundred," was the greeting. "Meet us in Rome in '93, where coeducation has existed since Agnes of *Coronina* captivated with her mathematics and her beauty," was the parting word.

Right upon the heels of this innovation comes the Johns Hopkins College, where post graduate medical education of the highest order is assured woman; but she will have to do it herself. Then the Brooklyn Board of Health, through its successful health officer, has appointed from its civil service list, two of our number upon its sanitary work. Surely 1890 has been propitious!

There will never be more women in medicine than will be needed. The great advance made

in gynecology owes more to her entrance into medicine than will ever be told. None of you would be willing to return to the time of the untrained nurse, with her snuffbox, catnip tea and gin.

The first intelligent nurse at Bellevue was a medical woman student, who entered as a nurse to obtain the knowledge otherwise inaccessible to her. The cruel neglect and want of delicacy found in this institution, where help was taken from the workhouse paupers, suggested the necessity for reforms, which have culminated in the enlightened system for the education and training of nurses, which is one of the blessings of the age.

We might say that the work in this line in Germany is done by the Lutheran Sisterhood, who do through religious duty what our trained nurses do for the large remunerations which we pay them. And the success of surgery is due to the cleanliness and care given by this class, whether from duty or fee.

The woman physician stands to-day, side by side, not as a rival, but as a helper, to her brothers in the profession. Then open wide every avenue of learning to her! Only the best will satisfy her now. It is such a pity that so much vital force should be expended in hewing out new roads for learning. I returned from that great gathering at Berlin, fully believing that only upon the foundation of a university training, with ancient and modern languages, may the Western student hope to cope in knowledge with the scholars of the Old World, in scientific and medical researches in the future, without regard to sex.

THE CHAIR OF SURGERY IN RUSH MEDICAL COLLEGE.

Introduced by Address, delivered before the Class, April 1st, 1891.

BY N. SENN, M.D., Ph.D.,
OF CHICAGO.

PROFESSOR OF SURGERY IN RUSH MEDICAL COLLEGE, ATTENDING
SURGEON PRESBYTERIAN HOSPITAL.

Within the short space of four years ruthless death has twice vacated the Chair of Surgery in this college. On both of these sad occasions the faculty, students and alumne felt that an irreparable loss had been sustained. To fill the Chair of Surgery made vacant by the death of men who have distinguished themselves in their profession by honest scientific work, and have endeared themselves to their colleagues and students as exemplary and masterly teachers is by no means an easy task, hence the anxious inquiries from all sides and everywhere: Who shall be the successor? Who shall continue the work left unfinished? Rush Medical College has always been justly proud of its Chair of Surgery. Its founder was a surgeon of world-wide repute, and there can be no doubt that from its very beginning the

men who have occupied this chair have been the great magnet which has attracted an increasing number of students from year to year. I am not saying too much, if I make the claim, that the Chair of Surgery in this school, with the immense clinics attached to it, stand to-day, in the estimation of the profession and the people, second to none in this country.

The faculty of this college has entrusted me with the work commenced by the immortal Brainard, the work so faithfully and ably conducted by the genial and scholarly Gunn, the work brought up to the present immense proportions and importance through the heroic labors of Parkes, whose untimely death is now the cause of universal sorrow. To be chosen as successor of such men should satisfy the goal of ambition of any man. To be the fourth in a genealogy of a group of such surgeons in the oldest and most famous institution for medical education in the great Northwest is a mark of distinction which I fully appreciate, and which I shall make a faithful endeavor to merit by earnest devotion to the duties imposed, and by contributing my humble share towards making this great city what it surely will be in less than twenty-five years—the most important medical centre in the United States.

Brainard, the founder of this institution and the first occupant of the Chair of Surgery, was a great surgeon, a gifted teacher, and an original investigator. His giant intellect was not content in acquiring, practicing and teaching what was known at his time, but sought new fields for exploration, and the knowledge thus gained was freely infused into his students. Brainard's work in the field of experimental surgery brought him an international fame, and his name will be quoted as long as books on surgery will be printed. His work has not only left numerous permanent impressions in surgical literature, but it created a stimulus which took possession of his students and the progressive surgeons throughout the civilized world, leading them away from the old well-beaten paths into new, unexplored territories awaiting the advance column of original explorers. It is difficult to estimate the importance and magnitude of his work in this direction, but hundreds of his students scattered all over this country still remain living witnesses of his zeal, industry and ability as a surgeon, teacher and scientist. They are to be envied for having received their first surgical knowledge from one of the greatest, and certainly from the most original surgeon that America has yet produced.

Professor Gunn assumed a responsible position when he succeeded Brainard. That the faculty acted wisely in securing his services has been abundantly shown by his marvellous success as a teacher and the ever-increasing prosperity of the college under his watchful eye and judicious guidance. Gunn loved this institution dearly

and jealously watched its interests. He was more than a friend of every one of its graduates. He was not only familiar with the current surgical literature but also added his share of original scientific work. His love for original research seemed to increase as he grew older. His contributions to our knowledge of the mechanism of dislocations were the outcome of patient experimental work and philosophical reasoning, and mark a decided advance in this important department of surgery. His last paper on this subject is a masterly product and should be in the hands of every student, as it is a genuine *multum in parvo*, containing all essential facts pertaining to this difficult chapter in surgery in a nutshell. Although the faculty, the students, and every graduate felt keenly the great loss sustained by the death of Professor Gunn the action of the faculty was plain in the selection of his successor. Professor Gunn made ample provision to meet such an emergency during the whole time he was connected with the college. He selected and trained his own successor. The late Professor Parkes was well aware of this fact and made the best of his excellent opportunities. For fifteen years he taught anatomy with an enthusiasm and ability unsurpassed in this or any other country. Under his tuition thousands of students learned to regard the study of anatomy as a pleasant and profitable pastime instead of an uninteresting drudgery, as is so often the case when taught by one less skilled and conversant with his subject; and left the college perfectly familiar with the essential basis of a thorough knowledge of surgery. During all this time Parkes was the right-hand of his teacher of surgery, master and student assisting and stimulating each other in their respective work. How well he had prepared himself for his life work is shown by his short, but brilliant career as professor of surgery. His accurate knowledge of anatomy combined with his familiarity with modern surgery made him a brilliant and successful operator. His skill as a surgeon was soon recognized and was eagerly sought for far and near. His success as a surgeon has made this clinic what it is to-day, one of the largest and most profitable on the continent. As a teacher few equalled, none surpassed him. Like his predecessors, Parkes was not only a distinguished surgeon and great teacher, but also an enthusiastic, faithful worker in the field of original research. His valuable experimental investigations on the surgical treatment of penetrating gunshot wounds of the abdomen have laid the foundation for the rational treatment of these injuries for all time to come. His experimental and clinical contributions in this department of surgery have erected a monument to his memory more enduring than marble and more precious than bronze.

His untimely death is surrounded by halos of

peculiarly sad and distressing circumstances. The cold hand of death touched him in the prime of life. The final message reached him at a time when he was just beginning to reap a well-earned abundant harvest, and when in full view of a professional career unparalleled in usefulness and prosperity. His pen dropped from his busy hand after he had nearly completed what promised to be a most interesting and valuable work on abdominal surgery. His work as a teacher came to a sudden end near the close of the session and just before the Commencement exercises at which one of the largest and best classes left the portals of Rush Medical College in deep mourning over the loss of their favorite and most esteemed teacher. His restless soul departed from this world in the absence of his family, and the last moments of his life were not cheered by words of love and parting kisses from those nearest and dearest to him.

The life of Professor Parkes furnishes a striking illustration of what can be accomplished in a little more than half a life-time by well-directed, hard study; close application to professional duties and unremitting work in search of new facts. In appearing before you as his successor, I am free to confess that it is with a keen appreciation of my many shortcomings. In resuming the work as a teacher of surgery in this institution, I am encouraged by the prospects that I shall, in the near future, be joined in my work by an associate, a surgeon of more than National reputation. If the combined work of both of us shall accomplish for the college and students what was done by Brainard, Gunn and Parkes my ambition and expectation will have been realized. I have left a lucrative practice, a pleasant home, a large circle of professional and social relations, a prospering, wide-awake State, and a beautiful city, and have come here to devote the balance of my life to the interests and welfare of this college and its students. I am fully conscious of the fact that I am coming at a time when the methods of teaching are undergoing a radical change. In the future recitations will largely take the place of didactic lectures. Text-books will be written with this special end in view. This comparatively new method of teaching surgery will be made a prominent feature during the next and all subsequent sessions. This new departure will necessarily change somewhat the plan and scope of clinical teaching. It is my intention to carefully arrange and classify the available clinical material in my department which will enable me to combine didactic with clinical instruction. This change will result in a reduction of the number of cases brought before the class, but will prevent unnecessary repetition, and thus save more time for the study and examination of pathological lesions, which will be a sufficient inducement for the students to attend every clinic,

take full notes of what they see and hear and to remain from beginning to end. May God grant that the work entrusted to me and my absent colleague may be worthy of our predecessors, and equally efficient in relieving suffering humanity, in advancing the interests and increasing the sphere of usefulness of this college, and finally, in giving to its students a thorough knowledge of the science and art of surgery.

MEDICAL PROGRESS.

Therapeutics and Pharmacology.

RESORCIN IN RODENT ULCER.—BOCK (*Monats. f. prakt. Derm.*, No. 4, February, 1891) has obtained unusually good results by treating rodent ulcer with Unna's resorcin plaster, and selects two cases as examples. In one there was an ulcer an inch and a half square, which had lasted ten years. The surface was everywhere open, moist, and suppurating. The resorcin plaster was applied and changed daily. After a few days considerable improvement was observed, and after two months the whole ulcerating surface was healed over, only here and there being a minute oozing point. In the second case the ulcer had lasted for six months, and was about a centimetre square, with raised infiltrated borders. Excision was declined (the patient was about 82 years old), and resorcin plaster was applied. In seven weeks, when the patient was accidentally met, the ulcer was found to have been long healed, and treatment given up. A shallow, slightly reddened cicatrix remained. Unna (*ibid.*) reports a similar case.

HYDROCELE TREATED BY INJECTIONS OF CHLORAL HYDRATE.—DR. MARC SÉE has made use of hydrate of chloral in the treatment of two hundred cases of hydrocele. According to him chloral has the property of coagulating the blood and serous fluids, and thus obtains a limited range of usefulness in surgery. It may be made to take the place of the iodine solution very generally injected into hydroceles. He has used chloral in this way repeatedly and without any untoward results. For this purpose he has employed a ten per cent. solution of the drug, which he has injected, either slowly or all at once, into the sac. He has used one ounce to each injection. Two or three days afterwards a large effusion of fluid occurs, which is soon entirely reabsorbed. When the walls of the hydrocele are very much thickened, neither the injections of chloral nor any other substance are of much avail, and the use of the knife becomes the best treatment. From an abstract in the *Lancet*, which has supplied us with the above data, it further appears that some success has followed the use

of chloral injections in the neighborhood of varicose veins, as they cause a gradual coagulation of the contained blood, and a contraction of the veins themselves.

NOVEL TREATMENT OF INGROWN TOENAIL.—DR. PUERCKHAUER recommends a novel, simple, and at the same time competent treatment for ingrown toenail: A 40 per cent. solution of potassa is applied warm to the portion of the nail to be removed. After a few seconds the uppermost layer of the nail will be so soft that it can be scraped off with a piece of sharp-edged glass; the next layer is then moistened with the same solution and scraped off; this must be repeated until the remaining portion is as thin as a sheet of paper, when it is seized with a pinicette and lifted from the underlying soft parts and severed from the other half. The operation does not require more than half an hour's time, is painless and bloodless, while the patient is delivered from his suffering without being disabled even for an hour.—*The Pittsburgh Medical Review*.

A SIMPLE TREATMENT OF CORNEAL ULCERS.—M. VALUDE, one of the ophthalmic surgeons of the Quinze-Vingts Eye Hospital, communicated to the Académie de Médecine on February 10, a new method of treating those troublesome cases—ulcers of the cornea—so simple in its application, and, according to its inventor, so successful in its results that it cannot fail to be generally adopted. Hitherto corneal ulcers complicated with hypopion have been treated by puncture either by the knife or thermo-cautery, this operation having frequently to be repeated, and too often leaving behind it opacities, if not actual staphyloma. For this unsatisfactory method M. Valude substitutes a simple dressing, consisting of a pad of salol gauze, which, with a moistened gauze bandage, effectually seals the eye and maintains a certain amount of compression. Before being applied the eye is carefully disinfected. The dressing is not renewed until after three or four days have elapsed, when the ulcer is found to be already healing, and the collection of pus in the anterior chamber much diminished. M. Valude states that the cornea tends to regain its original transparency without any opacities. In corneal ulcers uncomplicated by hypopion M. Valude, relying on his experience of fifteen successful cases, asserts that this new treatment is *the treatment par excellence*.

COCAINE INCOMPATIBLES.—Cocaine is used in manifold mixtures, and often brought in contact with substances with which it is entirely incompatible. A. Brummer states that it is frequently prescribed with silver nitrate in ointments, when, as is probably not known to the prescriber, decomposition of the hydrochloride ensues with

formation of insoluble chloride of silver, and a corresponding change in the cocaine. E. SCHELL, in the *Eis-lothr Journ. d. Pharm.*, reports that if calomel and cocaine hydrochlorate are rubbed together chemical reaction sets in. Mercuric oxide, too, if dispensed in form of ointment containing cocaine hydrochlorate changes, so that the ointment, instead of producing an anæsthetic effect upon the eyes, produces an exceedingly irritating one. This is due to the formation of oxy-chloride of mercury, the quantity of which depends on the amount of cocaine used, the intimacy of its mixture with the oxide, and the age of the ointment.—*Apoth. Ztg.*

TREATMENT OF DIPHTHERIA.—DR. GUNTZ, of Dresden, has had great success in the treatment of diphtheria with bichromate of potash in water containing carbonic acid, which he has found by numerous experiments on animals, as well as in the course of extensive clinical observations, to be entirely harmless. For an adult 600 grams (about a pint) are ordered per diem, in which are dissolved 3 centigrams (about $\frac{1}{2}$ gr.) of potassium bichromate. The whole quantity is directed to be taken in about half a dozen doses, regarding which it is important to observe that they must not be taken on an empty stomach; a little milk or gruel should therefore be swallowed before each dose. Children, of course, take smaller quantities, according to age. They can be given the medicine in a tumbler mixed with some fruit syrup, and they do not generally object to it. At the commencement of the disease Dr. Guntz washes the mouth out with a 1 per cent. solution of permanganate of potash containing 0.1 per cent. of thymol, or with a corrosive sublimate solution of the strength of 1 in 3,000, taking care, in the latter case, that none is swallowed, and that the mouth is well rinsed with water afterwards. In the case of young children the pharynx must be brushed out with the solution. Sometimes iodoform is employed, being applied on the tip of the finger to the affected spots. Dr. Guntz specially remarks that potassium bichromate, though harmless in the way described, is by no means so when in pills, powders, or in solution in non carbonated water.—*The Lancet*.

SIMPLE TREATMENT FOR CHOLERA.—DR. HARKIN has proved the following method by actual experience: Blistering, collodion or any epispaste, is applied behind each ear and along the course of the pneumogastric nerve as far as the angle of the lower jaw. The object is to cause inhibition of the sympathetic in the abdomen by stimulating the vagus. The result is at once apparent; the purging and other characteristic symptoms cease, and the patients fall asleep long before vesication takes place, and awake cured, or at least tided over the dangerous pe-

riod. Counter-irritation with mustard or spice leaves might be useful in a similar way in the treatment of cholera infantum.—*India Med. Gaz.*

Obstetrics.

CAFFEIN IN PUERPERAL HÆMORRHAGE.—**MISKACHI** (*Centralblatt für Gynecologie*) recommends the hypodermic injection of caffein in puerperal hæmorrhage. He says that it produces quicker results than ergot, and it is at the same time a powerful stimulant. He begins with a dose of 20 centigrams, which is repeated until a desirable reaction is established. The insolubility of caffein may be met by mixing it with benzoate of sodium, the two substances readily dissolving in hot water.

Medicine.

SALOL IN THE GASTRO-INTESTINAL DISEASES OF CHILDREN.—Salol, administered by the mouth, does not undergo any change until it reaches the intestine, where it is acted upon by pancreatic secretion and decomposed into carbolic acid and salicylic acid. Its use as an antiseptic is modified by the action of the pancreatic secretion, and it has been employed for different diseases of the stomach and intestines in children. **BARR** has reported thirty-five cases of gastro-intestinal inflammation in which salol was administered. When the symptoms were those of acute gastro-enteritis, with vomiting of the food and copious stools of disagreeable odor, the use of salol, either pure or combined with an inert powder, was found efficacious. If the stools were lumpy and the vomited material mixed with bile, calomel alone gave better results than when combined with salol. When the stools are serious, in dysentery and in colic, salol should be mixed with a little opium to allay the tenesmus, or it may be combined with codeine or narceine. In the first period of acute gastro-enteritis, and in the chronic forms of entero-colitis, salol acts most efficiently. **Barr** gave salol in doses of three centigrams to children under six months of age, and from three to nine centigrams to those from sixteen to eighteen months, from nine to twelve centigrams to those who have reached two years. Salol is a remedy which is easily administered, and it is without toxic action. It is to be ranked among the approved intestinal antiseptics, which also include naphthol naphthaline, sulphide of carbon, and Belloe's charcoal. The author used it in the summer of 1889, combined with oleo-saccharate of canella, in four cases of infantile cholera, and with very encouraging results. Lowenthal has used salol to prevent the proliferation of the bacillus of cholera and the formation of toxine, which is produced by contact of the bacillus with the pancreatic secretion, in the midst of peptonized albuminous matter. In his experiments he used tubes containing an infected paste, introducing salol into some of the tubes, and leaving it out of

others. Some of the latter was introduced into mice. Some of the mice died and the others became very sick. Other mice were inoculated with material which contained salol. No effect was produced because the toxic secretion of the bacilli could not act upon the pancreatic contained in the material of inoculation, while the salol was decomposed by the pancreatine into carbolic and salicylic acid.—*Archives of Pediatrics.*

Surgery.

THE OPERATIVE TREATMENT OF PERITYPHLITIS.—**PROFESSOR SONNENBERG**, of Berlin, closes an interesting article which is quoted by the *International Journal of Surgery* from the *Berliner Klinische Wochenschrift* as follows:

1. We must strive by all possible means to differentiate clinically between the simple inflammatory and the purulent forms of perityphlitis. The serofibrinous exudations, which usually result from fecal obstruction in the cæcum and colon, are generally reabsorbed in healthy persons, even if they are extensive, and do not require surgical interference. It is only in patients suffering from tuberculosis or acute or chronic intestinal diseases that these exudations may become purulent in consequence of perforation, and they then require very simple surgical procedures, as general peritonitis is extremely rare in these cases.

2. Purulent exudations, originating in the vermiform appendix, cannot be absorbed. In these cases the disease has been preceded, at greater or less intervals, by attacks of colicky pains in the ileo-cæcal region. The exudation, which is circumscribed and small at the beginning, is the result of gangrene and perforation of the appendix, and is of purulent or sero-purulent character. The experienced and careful physician will usually be able to recognize these forms of purulent perityphlitis with certainty.

3. The more superficial a purulent perityphlitic exudation is situated, the earlier an operation is indicated, that is, within the first few days after the occurrence of the initial symptoms. A simple incision is sufficient in most cases, owing to the presence of adhesions.

4. If, however, the exudation is small, indistinct and deeply-situated, we should perform the operation in two sittings, as early as possible after the beginning of the disease, especially if the resistance and dulness disappear on account of the increasing meteorism; for experience teaches that by proceeding in this manner we are able to discover again the purulent deposits, and lay them open without injury to the peritoneum and risk to the patient.

By this treatment, the operation is deprived of its dangers, and even in doubtful cases this procedure is a rational one. The surgical methods described above will enable us to avoid the un-

certain results of a spontaneous cure, the dangerous recurrences, and the occurrence of fatal general peritonitis in apparently mild cases.

Pathology.

CHOLERA NOSTRAS.—IN a paper read before the Société Médicale des Hôpitaux on February 6th, Drs. GILBERT and GIRODE describe the researches they have made in regard to some cases of cholera nostras. The chief interest lies in the bacteriological work. The stools in some of the cases yielded almost pure cultivations of Escherich's bacillus. Cultivations were also made from the faces on different media, and numerous colonies were also obtained from the cerebro-spinal fluid, but not so many were yielded by the blood of the liver and spleen. The fluid squeezed from the lungs produced, in addition to the pathogenic bacteria, organisms morphologically similar to the pneumococcus. Although certain organic disturbances, such as high temperature, favored the development of the bacillus, as shown by the fact that when such occurred pure cultivations could be easily obtained from the stools, the authors would not imply the reverse order of things—that the high temperature, etc., was caused by rapid multiplication of the organism; they considered that cholera nostras is not always a symptom of a local lesion of the intestine, and that the germs were able to pass through the walls of the intestine, invading the body, and so bringing about a new morbid type—the infectious form of the disease. They were also of opinion that the bacillus of Escherich was not the only choleraic microbe in this climate. Finkler and Prior have also found a bacillus in the alvine evacuations of patients suffering from cholera nostras, very similar to the cholera bacillus of Koch. There are two suppositions which may be considered as regards the connexion of Escherich's bacillus with cholera nostras. In one the microbe may be concluded to be harmless before it enters the body, and may there develop its special pathogenic properties. The second idea supposes that the germs are widely distributed, and acquire their poisoning properties before entering the body, most probably doing so by means of drinking water. In the guinea-pig, if a pure culture of this bacillus be injected, it is followed by all the symptoms of a typical attack of cholera nostras.—*Lancet*.

CAN SIMPLE VAGINITIS BE DISTINGUISHED FROM THAT OF GONORRHOEAL ORIGIN?—If the confident assertions of various writers in the medical journals are to be believed, it is a matter attended with little or no difficulty to distinguish between a case of simple vaginitis and one of specific origin. Within the month we read the following from a well-known professor of gynecology: "It is very difficult to distinguish be-

tween specific and non-specific vaginitis, unless the microscope is used to demonstrate the presence or absence of the specific microorganisms characteristic of the disease."

The following, which we copy from the *Medical and Surgical Reporter*, seems to us to express the truth of the matter: "When in adults, the discharge has appeared suddenly, is purulent in character, and in its early stages has been associated with scalding pain on micturition, a hot and tender vagina with bright red points covering the mucous membrane, and with a red, velvety or granular os uteri, the probabilities are altogether in favor of gonorrhœa. And yet it is doubtful whether many men could be found willing to take the witness stand and declare positively, from the symptoms and appearances we have described, that the disease is gonorrhœa. The difficulty becomes still greater when the patient is not an adult but a child. Fortunately the cases of gonorrhœa in little girls are much less frequent in this country than they appear to be on the continent of Europe.

The discovery of the so called "gonococcus" by Neisser was hailed by many with enthusiasm. But it was scarcely discovered before assertions were made that it could be found in non-specific discharges, and that it could not be distinguished under the microscope from other bacteria, particularly diplococci. The latter conclusion is the one to which Vibert and Bordas have come. These writers have investigated, from a medico-legal point of view, the discharge present in the vulvitis of little girls, and declare that microscopic examination of such discharge never enables an expert to affirm that a particular vulvitis is or is not gonorrhœal. They find the gonococcus practically indistinguishable from the diplococcus—both bacteria, they say, have the same form and dimensions, the same arrangement in masses and heaps, and not in chains, and they stain alike and are alike deprived of their stain by alcohol.

It not infrequently happens that men are accused of having committed rape upon little girls, and sometimes vulvitis is adduced as one of the evidences of the violation. A vulvitis, however, has been found in a violated child although the person guilty of the rape was free from any evidences of urethral disease. It would seem to be impossible, therefore, in the present state of our knowledge of the bacteriology of gonorrhœa, to base upon it a diagnosis sufficiently positive to warrant a judgment by the court in a criminal suit. No doubt this difficulty will be overcome by-and-by, and perhaps by cultivation the gonococcus can be distinguished from the diplococcus. But just now the conclusion seems to be that our methods of detecting the gonococcus are not precise enough for medico-legal purposes.—Editorial, *Massachusetts Medical Journal*.

No. 68 WABASH AVE.,
CHICAGO, ILLINOIS.

All members of the Association should send their Annual Dues to the Treasurer, Richard J. Dunglison, M.D., Lock Box 1274, Philadelphia, Pa.

LONDON OFFICE, 57 AND 59 LUDGATE HILL.

SATURDAY, APRIL 25, 1891.

THE VALUE OF KOCH'S TUBERCULIN.

Never has a medical discovery led within so short a time to such an amount of observations, as have been recorded since KOCH first announced his discovery of a remedy against tuberculosis. Now that five months have elapsed since KOCH's first paper and many observers can speak of three months experience, a survey of the applicability of "tuberculin" seems proper.

1. *Its Diagnostic Value.*—Koch stated originally that no effects had been observed by him in healthy people from doses under about 1 centigram. He therefore considered a reaction of the system to a smaller dose, by fever, lassitude, diffuse pains, etc., absolutely characteristic of tuberculosis. The subsequent experience of others has shown that this rule is not without exceptions, hence it is at present only safe to say that "a systemic reaction on injection of less than 1 cg. of tuberculin in an adult is a very probable but not absolutely decisive indication of tuberculosis."

Numerous observers have injected the substance for diagnostic or experimental purposes in non-tubercular patients or healthy subjects. No very large statistics are as yet reported, but while some never obtained any reaction, others found a variable proportion of non tubercular people reacting to doses under one centigram. PEIPER tested twenty-two non-tubercular patients under careful observation. Of nineteen receiving 2 mg., four reacted; of twenty-one subjects eight responded to 5 mg., while of sixteen who were tested with 10 mg., twelve suffered with fever. MICULICZ reports that of ten healthy young men,

five reacted to 0.01 lymph, and five did not. Amongst twenty-five surgical, but non-tubercular patients, twenty-two showed no result on injecting quantities varying from 1 to 15 mg., while in three reaction was obtained. Many reporters state that in numerous instances reaction occurred in people who at the time were considered free from tuberculosis, but in whom the tuberculin made manifest a latent tubercular focus, as the subsequent history showed. Of great interest are the researches of Schreiber on forty new born children, who beginning with the utmost caution, found that he could increase up to 50 mg. without ever getting any reaction whatever.

While it has thus been learned that occasionally a non-tubercular human organism may respond by a general disturbance to a dose less than the average usually requisite, all observers agree that a local reaction indicates infallibly a tubercular lesion, as it has never been observed under other conditions. The local reaction shows itself by increased redness and swelling on the diseased skin or visible mucous surfaces, and by pain and tenderness in diseased bones and joints, often with increased secretion if fistulae exist, and redness and swelling of the fistulous tract. The reaction of the internal organs is sometimes, but not always, indicated by pain, while in the lungs an increase in the area of dulness and an augmentation of rhonchi often indicate the local disturbance induced by tuberculin. The local reaction is not invariably accompanied by fever, especially if it be slight. It is generally stated that it precedes the fever in its first beginning, the febrile disturbance being evidently dependent upon it. In leprosy GOLDSCHMIDT and BABES and KALENDERO have observed a very gradual and rather persistent, though temporary, change in the affected parts (viz., increased swelling and tenderness), which might be termed a delayed and protracted local reaction quite different from that in tubercular lesions.

While the typical febrile reaction begins generally between the fifth and twelfth hour after the injection, reaching its acme in about two hours, and lasts altogether from six to twelve hours if at all marked, various deviations from this type have been observed. Occasionally the whole febrile paroxysm is postponed some twenty-four hours. A few times a slight second rise of temperature has been observed on the second day. A

continuous febrile disturbance succeeding the acute rise of temperature has been shown by SONNENBURG to be due to the retention of increased secretion in surgical patients, and was relieved by him by free drainage. It indicated in his cases that the lesions were not merely tubercular, but due to mixed infection. Since this is the case also in advanced phthisis a pyogenic after-effect can be accounted for by retention of pus in the pulmonary as well as in the surgical cases. MIKULICZ, however, a competent surgeon, as well as others, have seen lasting febrile disturbance following the use of tuberculin, which could not be attributed to retention of secretions. It is generally admitted that in the latter instances tuberculin is of doubtful service, sometimes positively harmful.

It cannot be predicted from the weight or the condition of the patient, or the extent of the tuberculosis, how intense the reaction to a given dose of tuberculin will be. It can only be said that any increase of dose beyond the quantity necessary to produce a febrile reaction will render the reaction more intense.

The diagnostic value of the substance depends of course upon the certainty with which the tubercular organism will respond to it. It seems that a marked febrile disturbance can be avoided by beginning with small doses and increasing them cautiously. Some of the instances in which manifestly tubercular patients did not react by fever were evidently due to this mode of procedure. The Berlin observers, who have perhaps the largest experience (especially GUTTMANN and EHRLICH), have pointed out that if it is desired to get a reaction for diagnostic purposes 1 mg. should be given to test the patient's susceptibility. If no reaction follows, 5 mg. should be injected after waiting four or five days, and if still doubtful, 10 mg. after another lapse of five days. If these procedures yield no reaction, the overwhelming probability is that the patient is free from tuberculosis. It must not be forgotten, however, that such rapid increase in the dose is justifiable only when it is very important to arrive at a diagnosis and other means of differentiation fail. Yet amongst the thousands of cases now on record there have been a few tuberculous patients who did not respond at all. But since these were almost invariably advanced lesions, the diagnostic value of tuberculin in de-

tecting the earliest localization of tuberculosis must be considered as very great, although not infallible.

IS INSANITY A CRIME?

There is an evident disposition in many quarters at the present time to assimilate the law of insanity to the criminal law. As is well known, for some years the State of Illinois has made trial by jury an essential prerequisite to admission to the asylums for the insane, and a similar provision is contained in a bill for the codification of the New York lunacy laws, recently introduced into the legislature of that State. We cannot but think legislation of this sort most unfortunate in every aspect in which it can be regarded. It is detrimental to the best interests of the insane; it is a needless affliction to their friends; it is an insult to the medical profession; it is a useless tax on the community, and there is no reason to suppose that it affords any protection against improper commitments that could not be secured in a more humane, expeditious and economical way.

The interests of an insane person require that he should be placed, as speedily as possible, and in such a manner as will be least likely to aggravate his symptoms, under the influences best calculated to promote his recovery. In a large proportion of cases—not all, by any means—this implies a restriction of the patient's liberty. In such cases, admission to a hospital specially organized and conducted for their treatment, may be the most valuable of privileges for its beneficiaries—none the less so for the fact that their mental condition prevents them, for the time being, from appreciating their needs. The questions involved are strictly medical, as much so as the diagnosis and treatment of a case of small-pox, or yellow fever. The law, in some cases, requires that persons suffering from these diseases should be restrained of their liberty and treated in special hospitals, but we do not remember ever to have seen it proposed that they should have the benefit of a jury trial, nor do we think that there is likely to be a very loud call for it on the part of those members of the legal profession who are so fearful that some one may be deprived of liberty without due process of law. In the one case as in the other, everything that throws needless delays or obstacles in the way of

the prompt application of proper treatment is a wrong to the patient. That such is the natural result of a jury trial, no one will be likely to question. The publicity that it involves makes the relatives of patients reluctant to take the necessary steps, the proceedings themselves involve delay, and there is always the possibility that the incompetence of jurymen to decide difficult questions of diagnosis may result in the failure of the patient to receive the treatment that is required for the best interests of all concerned. The very circumstances of being taken into court and put on trial, like a criminal, is calculated to exert an unfavorable influence on the minds of many of the insane, endangering their prospects of recovery.

The natural desire of any right-feeling person who has a friend or relative suffering from mental derangement is to keep everything concerning it as private as possible. To require the friends of the insane to do violence to all their best feelings in such a case—to make the extravagances, the follies, the indecencies of their dear ones a spectacle to the loafers of a court-room—is a hardship which nothing but the most imperious necessity can justify, and if useless, can only be characterized as an abominable cruelty.

Considered with reference to its bearing on the medical profession, legislation of this sort can only mean one of two things; either that physicians are less competent in their own business than the average jurymen, or that they are more likely to be swayed by improper motives in cases of this kind. We deny that reason or experience shows either to be the fact, and we have no doubt that, on this point, at least, our readers will agree with us that such a law is an unwarranted imputation on the intelligence and the integrity of an honorable body of men.

Legal proceedings of all sorts are known to be a rather expensive luxury, and one for which some one has to pay. The amount that has been expended in trials for insanity in Illinois would, if devoted to increasing or improving the accommodations for the insane, have made no contemptible addition to the funds for those purposes. But this is by no means the total cost of such legislation. The public must pay for the maintenance of those who, for want of timely treatment, become incurably insane, and for the damage that they may do while at large.

Probably no one would maintain that a jury trial is a benefit to those who are actually insane, or that it is of material benefit to the public in general. The ground on which it is advocated is the alleged danger that sane persons may be confined in hospitals for the insane, and that a procedure like that in criminal cases is a security against such a misfortune. Two questions are raised here, as to the reality and extent of the danger, and of the value of the protection.

As to the former point, it may be admitted at once that physicians are not infallible, and that, now and then, a person is improperly committed to a hospital for the insane. In the great majority of such cases, no serious hardship is inflicted. Some persons are temporarily crazy from drink; some are idiots and epileptics, in need of care, but not insane in the ordinary acceptance of the term; a few are delirious or stupid from fever or uræmia. In a very large proportion of cases, they are admitted with their own consent, as an alternative to confinement in a penal institution, either with or without criminal prosecution. Not a few of them have had the benefit of a trial by jury, and been improperly acquitted on the ground of insanity. The number of persons who, without having conducted themselves in such a manner as to throw reasonable doubt on their mental soundness, have been confined in institutions for the insane from improper motives is, we believe, extremely small. Compared with the numbers who are unjustly convicted of crime by juries, it would be ridiculously small. There is probably, for the average man, at least a hundred times the probability that he will be deprived of his liberty by the verdict of a jury, in a malicious criminal prosecution, than by physicians on a groundless charge of insanity, and the consequences in the former case are much the more serious.

But, taking the danger for what it amounts to, how much protection would a jury trial afford? In all cases presenting any difficulty the jurors would, in most cases, be entirely incompetent to judge of the value of the evidence. They must accept or reject the opinions of the physicians, and in so doing, they must be governed, not by an independent judgment of the facts, but by their impressions as to the competence and honesty of the witnesses. If they accepted the medical testimony, they would be useless; if they rejected it, they would probably go wrong. Any one who

thinks that it would be impossible for any one to be unjustly decided insane by a jury, or even that such an event would be improbable if interested parties should go to work and get up a case, must have a faith in the jury system that is very little affected by observation of its practical workings.

We protest, then, against all such legislation, as detrimental to the interests of all concerned. More particularly we protest against it as calculated to foster the feeling, already too prevalent, that insanity is a crime instead of a symptom of disease—a disgrace instead of a most pitiable misfortune. In the name alike of common sense and of humanity, we urge that an end be put to such foolish cruelty.

WHO OWNS THE PRESCRIPTION?

The *Philadelphia Medical and Surgical Reporter*, quoting from the *American Journal of Pharmacy*, embodies a legal opinion, the gist of the argument of which appears to be that the apothecary needs the filled prescription as evidence for his own or other protection and therefore retains the paper on the ground of convenience, "to warrant himself if a question shall arise as to correctness of conduct." "Evidently the only dispute can exist in a case in which the physician and patient have parted with the possession of the paper and it has lawfully come into the hands of the apothecary at the instance of the patient." The delivery to the apothecary is not virtually a transfer, nor is a new prescription requisite every time the order is sought to be filled. Says Mr. McMURTRIE, the utterer of the opinion, "there ought to be no doubt that the apothecary may, if he sees fit and is foolish enough to run the risk, put the paper in the fire. There can be no duty to produce it for inspection or to give copies, while it would be silly to refuse to do so, when reasonably demanded."

Notwithstanding the *ad captandum* vein, there is much logic in the opinion, albeit the profession too may have certain interests akin to those involved by the copyright. These self-same prescriptions are figments of the brain, made by this custom of repeating a menace to the future emoluments of the physician, but this is equally true of every other vocation in all civilized countries and cannot be made the subject of special legislation. To ourselves it has always seemed that the

patient did own the written order upon the apothecary—the former rather than the latter—and last of all the physician, who, being exempt from responsibility for the unauthorized use of what was once his commodity, is not required to give any warning in order to purge himself of the charge of being a *particeps criminis*. The risk as against public policy is mainly with the apothecary, especially in the matter of opiates, which may or may not call forth a coroner's jury censure. But this censure is only an inoperative substitute for a penalty, which at the utmost only entails a certain amount of notoriety, conjoined with a probable loss of business. The store-keeper who has sold a murderous pistol may have his regrets, but readily consoles himself with the reflection that he might as well have his price as any of his rivals. Criminal intent being absent, the law cannot well take cognizance of results. Besides the spirit of trade has so ordained, and every individual is interested in the principle of discretion in one way or another.

The whole question has been discussed in many medical societies from one session to another; argument has been pitted against intuition and simplicity has all but been evolved out of the complexities, and to what profit? The counter of the apothecary has settled it all with the package delivered without numerous questions. There may be nice points deserving of notice, but they can only be presented as lawyers' quibbles, not as Supreme Court decisions. We scarcely think that the apothecary deliberately intends to defraud his patron, the physician, of a fee, for he knows that the patient does not intend to return to him for medical advice and that he probably only gratifies a whim or mood. There are grievances to be sure, and notwithstanding the alleged blood-relationship between law and justice, they very frequently do not speak as they pass by.

THE PROPOSED PAN-AMERICAN MEDICAL CONGRESS.

We are advised that a resolution will be brought forward at the coming meeting of the Association recommending that appropriate action be taken to assemble in this country an INTERNATIONAL AMERICAN MEDICAL CONGRESS. Our people are probably aware that among the Latin-American schools on this Continent a standard of medical

education obtains which insures a high standard of attainment on the part of their alumni.

An American Medical Congress would serve to bring into closer, and as we believe mutually beneficial relations with North American institutions, the valuable laboratories, hospitals and other medical institutions of Havana, Rio Janeiro and Brazil. These Governments are fast becoming our Continental allies, in all commercial relations, and there is abundant reason for us to cultivate the utmost of friendly relations with the medical profession in each of the Governments on the Continent. We favor the holding of such a Congress, and hope that favorable consideration will be given to such resolution when it shall be presented.

EDITORIAL NOTES.

DON'T FAIL TO SEND DELEGATES to the meeting at Washington. Every local medical society in the United States, which is in affiliation with the Association is entitled to representation in that body and to a voice in its proceedings. Simply see to it that delegates are elected; that they are furnished with credentials, and that they attend and represent their constituencies in the coming meeting. Let the Permanent Members go as Delegates also. The advantage of a delegate is this: When the discussion of a question is ended the Delegate can vote, the Permanent Member can not. In the decision of the important questions now pending, votes alone will tell! Let every section of the Union send its full quota of DELEGATES.

HOW TO SECURE RETURN TICKETS.—Persons desirous of securing commutation rates upon return tickets from Washington, must note the following requirements:

1. A certificate must be obtained at the office where the ticket is purchased stating that you have paid full fare for your ticket to Washington.
2. At Washington a certificate must be secured from the General Secretary of the Association certifying your attendance.
3. That certificate must be presented with the one which you received when you purchased your ticket at the railroad office where tickets over your road are for sale, and with that certificate in hand you will be able to obtain return tickets over the roads elsewhere designated at *one-third rates*.

In this connection we desire to bespeak your kind consideration of the needs and comfort of our always genial and obliging General Secretary, Dr. Atkinson. He will devote abundant time and designate the place and hours for obtaining his signature, and during these hours the members should be in prompt attendance. We protest against a custom which more and more obtains, of waylaying him in his dressing-room, in public halls, at the banquets, and in the midst of general discussions, for the purpose of gaining that coveted signature. He is burdened with many duties quite as important, and in order that he may give due attention to this it is essential that you obtain your certificates at the appointed time.

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF PHYSICAL EDUCATION.—The sixth annual meeting of this association was held at Boston, April 3 and 4, Dr. D. A. Sargent presiding. An array of papers dealing with the physical education and elevation of the race were presented, many of the contributors being members of the medical profession. "The Delsarte System;" "Physical Education in Colleges;" "The Growth of Children;" "Physical Education in the Y. M. C. A.;" "Physical Training in the Regular Army;" "Some of Galton's Tests;" "The Muscular Strength of Growing Girls," etc., are among the subjects considered. One hundred and sixty new members were elected. The next annual meeting is to be held at Baltimore. A committee was appointed to petition Congress for the creation of a chair of physiology, hygiene and physical training at the U. S. Military Academy at West Point.

ON INDEFINITE TITLES.—Indefinite captions to articles in scientific periodicals are a delusion and torment, the very bane of indexers. Dr. Billings and others have repeatedly indicated to medical writers how good work may be partially nullified by the use of meaningless titles, such as "An Important Case," "An Improved Operation," "Ethical Question," "Useful Suggestion," "A Measure of Reform" and a thousand others that might be mentioned. When a writer has a valuable communication to make to the medical profession, he should so prepare it that it shall arrest the attention of the reader in pursuit of that particular kind of information, and be comprehended without unnecessary delay or

search. To do these two things, a great help is a precise and descriptive title, an outline in a very few words of the chief point contained in the contribution. If a writer finds that it is difficult to concisely state the object of his article, there is a strong presumption that he has nothing of importance to say to his medical brethren. Every pithy and instructive paper is worthy of a pertinent caption, and in ninety-nine cases out of a hundred such a caption can be formed with less than six to eight words.

FAULTY CONSTRUCTION OF A GOVERNMENT HOSPITAL.—A conflagration at the Naval Hospital, Brooklyn, narrowly escaped effecting the complete destruction of that institution. It is reported that the fire was occasioned by a faultily constructed chute for the disposal of sweepings and refuse from the wards. The members of the medical corps have repeatedly called the attention of the authorities at Washington to this inflammable wooden flue running from one story to another; but too much "red tape," or too little attention to duty, or both, resulted in its non-removal until the day of the fire, April 8, when the flames effectually destroyed it. Considerable damage was done to the hospital, but no lives were lost. The fire occurred in the daytime and was extinguished, by the aid of the fire department of the city, without much delay. The first principles of hospital construction would seem to interdict the construction or maintenance of combustible shafts or chutes such as that alleged to exist in this instance.

MEDICAL ITEMS.

INFLUENZA AT HONG KONG.—A very sharp epidemic of influenza has of late prevailed at Hong Kong, taking on all the characteristics of the same affection as observed in this country.

DIPHTHERIA IN IOWA.—Reports go to prove that this disease, which has prevailed quite freely for several months, has now greatly declined.

PIPERAZINE is a new uric acid solvent which promises to be a valuable addition to our list of remedies.

A FALLING-OFF IN CALIFORNIA.—According to the last issue of the Register of Physicians in the State of California there is a notable decline in the number of physicians seeking to locate in that land of fruit and flowers.

DIPHTHERIA IN NEWFOUNDLAND.—That a scourge of this kind has been existing in Newfoundland can be gathered from the following: Within the past two years 2,499 cases have occurred at St Johns, and as the population of the city is given as 30,000, it will be seen that the proportion of persons suffering was one in twelve. The rate of mortality has been one in five.

A LATE VIEW TOUCHING TUBERCULIN.—In an official report from P. A. Surgeon J. J. Kinyoun, detailed from the U. S. Marine-Hospital Bureau to study the methods of Professor Koch in the Hygienic Institute of the Berlin University, occurs the following: "I am more convinced that the remedy has but a limited range of usefulness, and should only be administered in the first stage of the disease."

TRANSACTIONS OF THE BERLIN INTERNATIONAL CONGRESS.—The Transactions of the Tenth International Medical Congress are now ready for distribution among members. Foreign members must make application and forward postage. Copies have been placed on sale in London.

TYPHUS FEVER IN NEW YORK CITY.—A case of this disease recently occurred at Bellevue Hospital, ending fatally. Until just before death it was quite impossible for the physicians in attendance to arrive at a diagnosis. Active precautions have been taken against the disease spreading abroad.

YELLOW FEVER ON STEAMSHIP FROM BRAZILIAN PORTS.—The steamship Dryden, from Rio and other Brazilian ports, arrived in New York Harbor, April 9, infected with yellow fever. Three deaths from the fever occurred among the crew during the passage northward. All three cases began and terminated between March 11 and 22; and no other cases arose after the latter date. The ship was detained at Quarantine for disinfection and was ordered to be kept there under observation for a period of five days.

INFLUENZA.—Dr. Benjamin Lee, of Philadelphia, has made a report based upon a consideration of upwards of 41,500 cases of influenza. We merely desire to say in this connection that if numbers are sought upon which to rest conclusions Dr. Lee will do well to place himself in communication with Chicago physicians.

TOPICS OF THE WEEK.

THE POSSIBILITIES OF MEDICINE.

At the recent commencement exercises of Long Island College Hospital Professor T. Gailliard Thomas, in giving the concluding address, spoke as follows:

Even in these un sentimental days many men chose their occupations more because of attending dangers and chances of heroism than from any less romantic notion of their usefulness. Thus the youth of a smiling country are persuaded to risk their lives on the sea, and the painter in the hope of fame starves at his work in the attic. Young men would willingly lay down their lives for the glory of a Sheridan or a Farragut. Arms, literature, art, law, divinity, all had bright and glorious rewards for those who had the courage to aspire to them and patience to suffer for them, the industry to work for them and the genius to obtain them. Think you, continued the speaker, that the science of medicine, founded 400 years before the birth of Christ; the chosen work of our Saviour himself; the most far reaching and benign of all modern pursuits, stands alone in its inability to reward its votaries? Far from it. Look back with me into history, and I shall not be called upon to take you into the fields of ancient history, even, and it will go hard but I shall make you agree with me that of all callings, all pursuits, all professions, the rewards of medicine are greater, more lofty, more desirable and more endearing than those of any other in existence. His hearers would agree that he who had done the greatest good for his fellowman had, in the doing of, won the greatest rewards in earth's possessions, even if no mortal man knew of the deed but him. The forces of civilization work hand in hand for the common good. All the forces of intelligence, law, the fine arts, religion and medicine were all contributing their quota. Hygiene—the science of cleanliness—as taught by medicine, had wiped off the globe the terrible scourges which made the dark ages so terrible. Cholera, the dread monster, had been almost totally shut up in its birthplace in Asia and checked in its wanderings over the world. Quarantine had transferred yellow fever from a universal menace into a local distemper. Small-pox had been lashed to hell by the agent vaccination, and like a whimpering hound was held securely in leash. The work of medicine had far more numerous conquests than even those enumerated. So wonderful, so startling, so extraordinary were those results that he feared his non-medical hearers would suspect him of boasting if he read the full record of the proud achievements of medicine during the past hundred years. But conquests in the past in no wise curtailed the possible achievements in the future. One great initial discovery ever opened the way for numberless others equally as great to be made. This was illustrated by the microscope, by the telescope, by the circulation of the blood, by steam and electricity. The discovery of the transmission of disease by bacilli had brought the students of to-day upon a plane far more elevated than that which even the youngest of their teachers occupied upon his graduation. The present students' possibilities in medicine

were proportionately greater than his were, and it was their function to profit by their good fortune.

The speaker declared if he had the power to accomplish one wish in his life he thought he would select the destruction of the process by which alcohol was created. If that were denied him, the power of stamping out forever those contagious diseases which fill our graves with curly heads and dimpled cheeks and our homes with sorrow that knows no comforting. He would destroy those terrors of the household, scarlatina, diphtheria and the host of contagious maladies which went hand in hand with them. The first of these wishes was impossible of attainment. But not so of the second. The way of its accomplishment was open to every man with willing hand, determined mind and intelligent brain. Surely it was not too sanguine a prediction that the next century might see the extinction of contagious disease. Elaborating this point, the speaker pointed that since 1799, the date of Jenner's discovery of vaccination for small-pox—and unless the claims of Pasteur and Koch should prove valid—no other contagious disease has been prevented by the elaboration of the brilliant idea of inoculation. Diseases were also checked by certain drugs which seemed to have the power of destroying their bacilli cause; but with these but two diseases had been checked in the history of medicine. Here was the field and it remained but for the student of to-day to work in it. There was everything to accomplish and the road was made clear before him. After formulating his suggestions in detail and giving illustrations of how genius had labored long to solve some of the simplest problems of life the speaker said in conclusion:

The motto of the New York Academy of Medicine, coming down from mythological times, is this: "*Hominibus deos accedunt hominibus dando salutem.*" "Men most nearly resemble the gods when they afford health to their fellow-men." If, as seems now highly probable, Robert Koch should succeed in curing and preventing tubercular disease in its various manifestations, what greater reward could he possibly ask for than the pleasure which he must feel when the reflection to which this motto gives rise comes to his mind. The reward of the physician whose happy discovery stamps out a disease which before his day slew its thousands, comes from the hand of no Emperor; his glory from the appreciation of no applauding multitude; his renown from the pen of no fulsome historian. For him the victor's crown comes from the hand of the immortal God; his glory from the satisfaction of doing a great and glorious work; his renown from the gratitude of his fellow-men! The "great awakening light" which blessed the eyes of Abou Ben Adhem, not the imperial purple which decked the shoulders of the mighty Julius, constitutes his diadem and causes a halo to shine around his head! In the golden days of chivalry, when a young knight was to receive the accolade and become the defender of the weak and the redresser of wrong, he was required to spend an entire night in cathedral or other solemn place, reflecting upon the purity, the beneficence and the grandeur of his new office, and in forming the noble resolve to make of it no trade, but to administer his duties with the love of

man in his heart and the glory of God in his soul. Let this night and these exercises bear to you the relation of that vigil night of old! Medicine is the noblest of professions; the meanest of trades. Unless you can live lives of purity, of virtue, of honor and of honesty, seek a livelihood elsewhere and insult not the gods by striving through base methods and ignoble ambitions to resemble them! Will you not now fully agree with me when in closing this address I ask you whether the possibilities of medicine are not really greater than those of her sister sciences and arts? Will you not accord in my postulate that arms, arts, literature, science, all have their rewards, but that not one of them surpasses in the magnificence of its gifts those of which the godlike science, medicine, is capable? When, a quarter of a century hence, I meet with one of you, as we both wend our ways along the highway of life, my locks as white as the driven snow and yours as white as mine are now, come up to me, report yourself as a member of the graduating class of the Long Island College Hospital of 1891, and tell me which one of the beneficent discoveries which the next twenty-five years are sure to bring forth has been the means of causing you to resemble the gods and enrolled your name "among the few, the immortal names that were not born to die;" and I, recalling at once to mind you and this pleasant evening which has made us acquainted, will bid you God-speed, even as I do to-night.

THE PHONOGRAPH IN MEDICINE.

The applicability of the phonograph to the record and demonstration of defects in speech has been well illustrated during the past week at the Royal Medical and Chirurgical Society and at the Hunterian Society. At the first-named Dr. Hale White and Mr. Golding-Bird were enabled by means of this instrument to allow the Fellows present to hear the curiously defective speech of two children, and to contrast this with the improvement effected by treatment, for the subjects were present, and after the phonograph had given their past utterances, their present speech was demonstrated *viva voce* . The papers read by the above gentlemen and that by Dr. F. Taylor led to an instructive debate, which was further illustrated by some marked cases introduced by Dr. Hadden. The outcome seemed to be that these defects in articulation are probably of central origin, and not due to any mechanical interference with the organs of speech. Whether, as suggested by Dr. Langdon Down and Mr. Spencer Watson, the defect was primarily one of audition is a question certainly worthy of consideration. Another point raised was whether the defect should be considered one of speech or language, and some exception was taken by Drs. Taylor, Pye-Smith, and others, to the use of the term "idioglossia," which, however, was ably defended by Dr. Hale White. The other phonographic demonstration at the Hunterian Society was by Dr. Hughlings Jackson, who thus reproduced the characteristic speech of a subject of cerebro spinal sclerosis. There can be little question that the phonograph will ultimately prove very useful, especially in the preservation of certain anomalies of articulation, and its further extension to other sound phenomena in the range of clinical medicine may be justifiably hoped for.—*The Lancet*.

WORD-BLINDNESS WITH UNUSUAL FEATURES.

The following case was reported by Professor Mierzejewski at a recent meeting of the St. Petersburg Society of Psychiatry, and is given in the *Neurologisches Centralblatt* for December 15, 1890. A physician, fifty-six years old, had had syphilis in his youth, and for several years had suffered from chronic nephritis. In January, 1890, he had an attack of uræmic coma, which lasted four or five days. He had since had two other attacks of shorter duration. Some time after the third attack, which occurred last spring, the patient noticed that he had lost the power of reading, although he could distinguish the letters easily, and his sight in general was unchanged. Mierzejewski found the following, on examination: The patient sees each individual letter clearly, but is unable to join the letters into syllables or words. He writes without difficulty and correctly whatever is dictated to him, but can not read what he has written. He can write prescriptions in due form, but cannot read them afterward. He can make correct copies without understanding the meaning of the words copied. Numbers, however, he can read and pronounce correctly. The patient's sight is perfect, and the fundus of the eye is normal. There is no disturbance of speech, and the intelligence is unaffected. There is no change in sensation, motion, or the reflexes. After looking through the literature of the subject, Mierzejewski concludes that this is the first case of word-blindness as yet reported in which the ability to distinguish the single letters was retained, and he calls it *cæcitas syllabaris et verbalis, sed non litteralis*.—*N. Y. Med. Jour.*

THE NAVAL MEDICAL SERVICE.

Mr. Tracy, Secretary of the Navy, is evidently no friend of the medical profession, nor is he very keen for the improvement of the *personnel* of the service, if one may judge from the following Washington despatch printed in the *New York Times*. The writer says:

"The medical corps of the Navy is still experiencing considerable difficulty in filling vacancies in the grade of assistant surgeon. Several candidates have recently been examined by the New York Board, but none was successful. The San Francisco Board has been dissolved because no candidates presented themselves. The medical colleges are now being canvassed by tempting circulars sent out by the Navy Department. The reluctance felt by students toward entering this branch of the Government service is obvious. Until Congress has increased the pay and conditions aboard ship of assistant surgeons, medical officers say that it will be impossible to keep the corps recruited to its full quota unless the standard of examination is reduced. This Secretary Tracy has absolutely refused to do."

The Naval Department is expending enormous sums in the building of ships; but, after all, these new monsters of the sea cannot be efficiently utilized without a high class of officers and men. Money expended in promoting this end would be wisely spent, and it is difficult to understand why, when millions are spent on experimental ships and guns, a few thousands cannot be used for raising the standard of the medical service to that of the army. As it is now, it looks as though it was involuntarily boycotted.—*Medical Record*.

PRACTICAL NOTES

PAINLESS CIRCUMCISION.

The suggestion of Dr. Overall, strongly endorsed by Dr. Storch, for producing anaesthesia of the parts to be operated upon, is as follows: Of a twenty to thirty per cent. solution of cocaine let ten or fifteen drops be pressed into the preputial opening with a blunt-pointed syringe and retained by pressure as the syringe is withdrawn. Let the parts be so manipulated that the entire preputial mucous membrane shall be in contact with the fluid ten or fifteen minutes. At the same time the integument where circumcision is to take place should be sprayed with the following mixture:

R. Chloroform, ʒ ijss.
Ether sulphuris, ʒ iv.
Menthol, grs. xv. ꝑ.

Continue the spraying of the parts until complete anaesthesia is produced. Following this procedure the operation is painless.

If the operation be performed for enuresis of long standing, the following medication is recommended:

R. Atropiæ sulph., grs. ij.
Aque distillatæ ʒj. ꝑ.

Sig. One drop for each year of the age of the child at 4 o'clock and at 7 o'clock, increasing the dose if no effect is produced after one week.

WHAT SHALL BE DONE FOR A COLD IN THE HEAD.

It may not be always possible to break up a cold. Sometimes during the congestive stage, anything which will allay irritation will suffice. The person who feels a cold coming on should instantly betake himself to bed, drink a cup of hot ginger-tea, and make use of a snuff like that which was proposed several years ago by Dr. Ferrier:

R. Morph. sulph., gr. j.
Bismuth subnit., ʒ iij.
Pulv. acaciæ, ʒj. ꝑ.

The insufflation of a little morphine at the commencement of a cold in the head is sometimes attended with very happy results. Quinine as an abortant in commencing cold is much in use; the dose should be somewhat large; Dr. T. J. MacLagan says ten grains. Its efficiency is, however, rather problematical. Doubtless, menthol is one of the best local applications in the early stages of coryza. It may be used in the form of an ointment (menthol one part, vaseline thirty parts), or as a spray with liquid alcoholene. A formula which may do good service is the following: Menthol, one part, liquid alcoholene, thirty parts. A special spray atomizer, such as sold by all the instrument makers, is needed for the effective use of this combination. Menthol seems to kindle con-

gestion to the mucous membrane; it is often followed by a profuse flow of nasal mucous with little sneezing. Breathing through the nose and mouth the steam of hot camphor water, and the internal use of carbonate of ammonia, are also recommended, and there is often utility in the production of active diaphoresis. Many of late years have claimed decided benefit from full doses of antipyrin, acetanilid, phenacetin, in the onset of colds; and, doubtless, these new remedies are more and more taking the place of the depressant diaphoretics.—*Boston Medical and Surgical Journal*.

PREVENTION OF PITTING IN SMALL-POX.

The pitting of small-pox has been entirely prevented by Dr. Lewintaner, of Constantinople, by antiseptic treatment, as follows: The entire head and face, except eyes, and the neck, are covered with plaster consisting of three parts carbolic acid and fifty parts each of olive oil and starch. The body is covered over with a mixture of three parts salicylic acid, thirty parts starch, and seventy parts olive oil. The internal treatment consists in giving quinine in acid solution.—*Wien. Klin. Woch.*

THE DEODORIZATION OF IODOFORM BY CREOLIN.

Dr. Ludwig Váci, a practitioner in Nagy-Karoly, communicates to the *Medicinisch-chirurgische Rundschau* his discovery of the power of creolin to deodorize iodoform. He had prescribed an ointment consisting of one part of creolin, two of iodoform, and twenty-five parts of vaseline. On the following day he was surprised that not only was the usual color of iodoform ointment changed, but that there was no smell of iodoform and only a slight smell of creolin. He points out how important it is in many cases that the presence of iodoform should not be known by its odor, and considers creolin the very best of all deodorizing drugs for the same. It not only does not irritate, but it is also itself a good disinfectant.—*Lancet*.

A POWDER FOR DYSPEPSIA.

Dujardin-Beaumetz (*L'Union Médicale*) uses the following powder for painful dyspepsia and gastralgia:

R. Bismuth subnit.,
Magnesiæ,
Crete præp.,
Calcii phosphatis ʒʒ ʒss. ꝑ.

Divide in pulv. No. XL. Sig. One powder before each meal.

FOR ENURESIS.

R. Tinct. cautharidis, gut. xvj.
Mucil. acaciæ, ʒj.
Pepsin cordial, P. D. & Co., ʒxvj. ꝑ.
S. ʒ ter in die.

—*The Country Doctor*

ASSOCIATION NEWS.

American Medical Association.

Preliminary Programme of the Forty-second Annual Meeting, to be held at Washington, D. C., May 5 to 8, 1891.

President's Address, by Wm. T. Briggs, Nashville, Tenn.

On General Medicine, by E. L. Shurly, Detroit, Mich.

On General Surgery, by Jos. M. Mathews, Louisville, Ky.

On State Medicine, by W. L. Schenck, Topeka, Kan.

Committee on Arrangements: Dr. D. C. Patterson, Chairman, 919 I Street, N. W., Washington, D. C.

Section of Practice of Medicine and Physiology.

"The Growing Importance of Chemical Studies in Medical Education and in Medical Research," by the Chairman.

Title not received, Wm. Osler, Baltimore.

"A Contribution to the Clinical Study of Protracted Pyrexia," by Wm. Pepper, Philadelphia.

"The Report of a Case of Fatty Urine accompanying an Abscess in the Right Iliac Fossa," by J. P. Connelly, Williamsport, Pa.

"The presence and significance of Albuminuria in Persons Apparently Healthy," by W. B. Davis, Cincinnati.

"The Diagnosis of Renal Calculus," by I. N. Danforth, Chicago.

Title not received, J. C. Wilson, Philadelphia.

"A Pathological Condition of the Lungs hitherto undescribed in this country, but which is not infrequent," by F. Peyre Porcher, Charleston, S. C.

Title not received, J. H. Musser, Philadelphia.

Title not received, W. J. Herdman, Ann Arbor, Mich.

"Some of the Remote Effects of Injury to the Brain in Delivery," by F. W. Goodell, Bennington, Vt.

"Physiological Properties of Living Tissue and their Relations to Practical Medicine," by N. S. Davis, Chicago, Ill.

"Recent Contributions to the Knowledge of Diptheria," by J. Lewis Smith, New York.

"Koch's Treatment of Tuberculosis," by John B. Hamilton, Washington.

"Prof. Koch's Method for the Cure of Tuberculosis and its Results in Pulmonary and Laryngeal Cases," by Karl von Ruck, Asheville, N. C.

"Tuberculin in the Treatment of Tuberculosis, with a Report of Cases treated at the Good Samaritan Hospital of Cincinnati," by S. P. Kramer, Cincinnati, O.

"On the Treatment of Chronic Phthisis," by Asa F. Pattee, Boston, Mass.

"The Relations of Syphilis to the Healing of Wounds and Surgical Diseases," by G. Frank Lydston, Chicago, Ill.

"Combined Internal and External Urethrotomy with Perineal Drainage," by F. W. McRae, Atlanta, Ga.

"Treatment of Umbilical Hernia in Children," by Jno. T. Chapman, Bessemer, Ala.

"The Management of the Epicyclic Fistula," by J. D. S. Davis, Birmingham, Ala.

Title not received, Wm. D. Hamilton, Columbus, O.
 "Two Cases of Intestinal Obstruction; Laparotomy; Results," by David Barrow, Lexington, Ky.

"Is Early Resection or Conservative Treatment Advisable in Coxitis," by Herman Mynter, Buffalo, N. Y.

"Infra Pubic Cystotomy," by John A. Wyeth, New York, N. Y.

"Electricity as a Therapeutic Agent; What is Needed to Determine its Merits?" by W. J. Herdman, Ann Arbor, Mich.

THEO. A. MCGRAW, Chairman,
 Detroit, Mich.

W. E. B. DAVIS, Secretary,
 Birmingham, Ala.

Section of State Medicine.

FIRST DAY.

Registration of the names of members present.
 Reading of the Minutes of the last meeting.
 Annual Address by the Chairman, J. D. Plunket.
 Report of the Committee on School Hygiene; D. T. Lincoln, Chairman.

Original Investigations on the Heating and Ventilation of School Buildings, by R. Harvey Reed, offered as a portion of the Report of the above-named Committee.

SYNOPSIS OF REPORT.

1. Date and time of day of inspection.
2. Name of building and room.
3. Number of cubic feet of air in room
4. Number of pupils present.
5. Outside temperature.
6. Temperature of room, at level of feet, head and ceiling.
7. Humidity outside.
8. Humidity in room, at level of feet, head and ceiling.
9. Kind of heating apparatus in use.
10. System of ventilation employed.
11. Number of cubic feet of fresh air supplied and of foul air discharged per hour.
12. Estimation of amount of carbon-monoxide present in the air of the room.
13. Estimation of amount of carbon-dioxide.
14. Consideration of amount of organic matter present in the air of the room.
15. Bacteriological examination of the air.
16. Miscellaneous remarks and suggestions.
17. Conclusions.

The discussion on this subject will be opened by Octavius A. White, New York, N. Y. The subject being one of great importance, the remainder of this session will be devoted to its discussion.

SECOND DAY.

Report of the "Committee on Meteorological Conditions of the Atmosphere and their Relations to coincident prevalence of Diseases," by N. S. Davis, Chairman.

"Sickness and Mortality in the Army of the United States," by Joseph R. Smith, Col. and Surgeon U. S. A. Medical Director, Department of Arizona.

"The Beneficence of Disease," by A. N. Bell, Brooklyn, N. Y.

Election of officers for the ensuing year.

THIRD DAY.

"The Disinfection of Excreta," by George M. Sternberg, Lieut. Col. and Surgeon U. S. A.

"Simple Methods of Sewage Disposal," by C. W. Chancellor, Secretary of the State Board of Health of Maryland, Baltimore, Md. Discussion on the above papers opened by Dr. Robert C. Davis, Member of New York City Board of Health, N. Y.

"The Coroner System in the United States," by Henry O. Marcy, Boston.

"Hygiene in the Rural Districts," By G. W. Jenkins, Kilbourn City, Wis.

"The Duty of the Government in the Prevention of Tuberculosis," by Lawrence E. Flick, Philadelphia, Pa.

Papers are also expected from Walter Wyman, United States Marine-Hospital Service; James F. Harrison, Gainesville, Virginia; and Peter H. Bryce, Secretary of the Provincial Board of Health of Ontario.

J. D. PLUNKET, Chairman,
 145 N. Spruce St., Nashville, Tenn.
 BENJAMIN LEE, Secretary,
 1532 Pine St., Philadelphia, Pa.

Section of Ophthalmology.

FIRST DAY—MAY 5TH. AT 3 P.M.

Remarks by the Chairman.

"The Causation and Management of Incipient Cataract," by Samuel D. Risley, Philadelphia, Pa.

"Treatment of Incipient Cataract by Electricity and other Measures," by J. Elliott Colburn, Chicago, Ill.

"Treatment of Immature Cataract, including (a) Report of Twenty-five Extractions of Immature Cataract; (b) Review of Various Modes of Artificially Maturing the Slowly Forming Cataract," by John F. Fulton, St. Paul, Minn.

"The Method of Performing Cataract Extraction," by J. J. Chisolm, Baltimore, Md.

"My Personal Experience in Cataract Extraction," by A. W. Calhoun, Atlanta, Ga.

"Practical Observations in the Treatment of Cataract," by Flemming Carrow, Ann Arbor, Mich.

"Pressure on Eyeball after Cataract Extraction," by Edward Jackson, Philadelphia, Pa.

"To what Extent are Personal Restraints Essential During the Healing of Corneal Wounds," by T. E. Murrell, Little Rock, Ark.

"An Improved Apparatus for the More Efficient Protection of the Eye after Cataract Extraction," by Geo. E. Frothingham, Detroit, Mich.

Discussion upon these papers, opened by H. Knapp and Karl Koller, New York; F. C. Hotz, Chicago, Ill.; J. L. Thompson, Indianapolis, Ind.; S. O. Richey, Washington, D. C.; P. D. Keyser, Philadelphia, Pa.

Voluntary Communications. Exhibition of Patients, Instruments or Pathological Specimens, etc.

Miscellaneous Business.

SECOND DAY—MAY 6TH.

Election of Officers (Time fixed by the By-Laws).

"The Centrad in the Reformed Numeration of Prisms," by B. Alexander Randall, Philadelphia, Pa.

Discussion opened by Swan M. Burnett, Washington, D. C.; W. S. Dennett, New York; Edward Jackson, Philadelphia, Pa.

"Further Contributions to Keratometry," by Swan M. Burnett, Washington, D. C.

Discussion opened by Geo. de Schweinitz, Philadelphia, Pa.

"Full Correction of Ametropia," by Edward Jackson, Philadelphia, Pa.

Discussion opened by G. C. Savage, Nashville, Tenn.

"An Analysis of One Hundred Cases of Astigmatism—Contrary to Rule and the Associated Symptoms," by Geo. de Schweinitz, Philadelphia, Pa.

Discussion opened by Wm. Cheatham, Louisville, Ky.
 "The Value of Weak Cylinders for the Relief of Eye Muscle Strain," by J. J. Chisolm, Baltimore, Md. The points made by this paper are—(a) Is it necessary to recognize the very small degrees of corneal irregularity? (b) Is it possible to work eyes comfortably with these slight errors? (c) Is the Eye Surgeon warranted in prescribing glasses as feeble as 0.25 cylinders? (d) What can such weak cylinders accomplish?

Discussion opened by Geo. T. Stevens, New York.
 "Paper on Myopia Based upon Recent Original Observations," by Francis Dowling, Cincinnati, O.

Discussion opened by A. W. Calhoun, Atlanta, Ga.; B. A. Randall, Philadelphia, Pa.; J. M. Kay, Louisville, Ky.; C. H. Hughes, St. Louis.

"Double Monocular Diplopia Dependent upon Cerebral Lesion," by J. H. Thompson, Kansas City, Mo.

Discussion opened by Charles A. Oliver, Philadelphia, Pa.

"A Study of Fifteen Hundred Cases of Ametropia," by A. R. Baker, Cleveland, O.

"Lessons of Fifteen Hundred Consecutive Refractive Cases in Private Practice," by George M. Gould, Philadelphia, Pa.

Discussion upon these two papers opened by J. A. Lippincott, Pittsburgh, Pa.

"An Examination of von Graefe's Doctrine of Antipathy to Single Vision," by George T. Stevens, New York.

Discussion opened by J. H. Thompson, Kansas City, Mo.

Voluntary Communications, Exhibition of Patients, Instruments or Pathological Specimens, etc.

THIRD DAY—MAY 7TH.

"Hæmorrhagic Glaucoma," by R. L. Randolph, Baltimore, Md.

Discussion opened by F. C. Hotz, Chicago, Ill.
 "Perimetric Observations on the Influence of Eserine and Iridectomy in Chronic Glaucoma," by Geo. de Schweinitz, Philadelphia, Pa.

Discussion opened by Karl Koller, New York, and Lewis H. Taylor, Wilkesbarre, Pa.

"An Experimental Study of the Comparative Mydriatic Effect of Atropia and Homatropia," by Horace M. Starkey, Chicago, Ill.

Discussion opened by Chas. J. Kipp, Newark, N. J.
 "Modern Ophthalmic Therapeutics," by W. T. Mitterdorf, New York.

Discussion opened by R. L. Randolph, Baltimore, Md.
 "Jequirity in the Treatment of Granular Lids," by J. G. Carpenter, Stanford, Ky.

Discussion opened by J. W. Wright, Columbus, O.
 "Papilloma of the Cornea, with Specimens," by S. C. Ayres, Cincinnati, O.

Discussion opened by H. Knapp, New York.
 "Prognosis in Treatment of Injuries of the Eye," by C. M. Hobby, Iowa City, Iowa.

Discussion opened by X. C. Scott, Cleveland, O.
 "Excision of Diseased Eyeball, Followed by Relief of Cerebral Derangements," by H. Moulton, Fort Smith, Ark.

Discussion opened by J. E. Coburn, Chicago, Ill.
 "Independent Relation of Tracoma and Blepharitis Papillaris," by Dudley S. Reynolds, Louisville, Ky.

Discussion opened by W. T. Montgomery, Chicago, Ill.
 "The Pathogeny of Sympathetic Ophthalmia," by F. C. Heath, Lafayette, Ind.

Discussion opened by George H. Goode, Cincinnati, O.
 "Choroidal and Retinal Hæmorrhages, their Many Causes, etc., Including Some Hitherto Unrecognized," by William H. Cheatham, Louisville, Ky.

Discussion opened by W. V. Marmion, Washington, D. C.

"A Case of Fibro-Sarcoma of the Neck attended by Temporary Paresis of the Third Nerve, Illustrated by Photographs and Microphotographs," by A. V. Würdemann, Milwaukee, Wis.

"An Analysis of the Sensory Changes and Conditions of the Ocular Apparatus as found in Imbecility, Epilepsy and General Paralysis of the Insane," by Charles A. Oliver, Philadelphia, Pa.

Discussion opened by E. J. Garliner, Chicago, Ill.; and D. B. Smith, Cleveland, O.

"Treatment of Irido-dialysis from Contusion. Partial Iridectomy with or without Suture," by Eugene Smith, Detroit, Mich.

Voluntary Communications, Exhibition of Patients, Instruments, Pathological Specimens, etc.

Chairman, LEART'S CONNOR, Detroit, Mich.
 Secretary, T. E. MURRELL, Little Rock, Ark.

Section of Laryngology and Otology.

President's Address, by Carl Seiler, Philadelphia.

"Surgery of Hard Palate Perforations," by A. G. Hobbs, Atlanta, Ga.

"Treatment of Enlarged Tonsils," by Chas. H. Knight, New York.

"Treatment of Follicular Tonsillitis," by A. B. Farnham, Milwaukee, Wis.

"Pharyngeal Tuberculosis, with Report of Cases," by T. V. Fitzpatrick, Cincinnati.

"An Effective Remedy in Diphtheria," by Jonathan Wright, Brooklyn, N. Y.

"Chronic Catarrhal Laryngitis," by M. Thrasher, San Francisco.

"Excision of Membrana Tympani," by C. H. Burnett, Philadelphia.

"Remarks on Excision of the Drum-head, Malleus and Incus, specially with reference to the method of employing his Instruments for the same," by Samuel Sexton, New York.

"Tinnitus Aurium," by Laurence Turnbull, Philadelphia.

"Myringoplasty," by C. W. Taugeman, Cincinnati, O.

"Nasal Cystoma with Specimen," by C. W. Richardson, Washington.

"Exostosis of Septum and Congenital Malformations," by Allen DeVilbiss, Toledo, O.

"Epistaxis: Its Etiology and Treatment," by S. J. Radcliffe, Washington, D. C.

"Report of Two Cases of Paralysis of Vocal Cords, and a Case of Lupus of the Nasal Mucosa," by E. E. Sattler, Cincinnati, O.

"Non-Topical Treatment of Throat and Ear Diseases," by E. Cutter, New York.

"Laryngismus due to a Congenital Valvular Formation of the Upper Orifice of the Larynx," by J. H. Bryan, Washington, D. C.

"Suppuration Occurring in Chronic Catarrh of the Middle Ear," by J. M. Ray, Louisville, Ky.

"Treatment of Ear Disease Following the Grippe," by Joseph V. Ricketts, Cincinnati, O.

"Some Results from Early Paracentesis in Middle Ear Catarrh," by J. E. Boylan, Cincinnati, O.

"Mouth Breathing not the Cause of Contracted Jaws and High Vaults," by Eugene S. Talbot, Chicago, Ill.

"The Relation of Tonsillitis to Rheumatism," by Hal Foster, Kansas City, Mo.

"The Influence of Nasal Obstruction on Phonation," by Max Thorne, Cincinnati, O.

(Papers, titles not yet announced, promised by A. W. McCoy, Philadelphia, and Frank H. Potter, Buffalo.)

CARL SEILER, Chairman,
 Philadelphia, Pa.

A. B. THRASHER, Secretary,
 Cincinnati, O.

Section of Diseases of Children.

"Lithæmia in Children," by William Pepper, Philadelphia.

"Prevention of Pulmonary Phthisis in the Adult by the Proper Treatment of the Lung Lesions of Childhood," by W. J. Stickler, Orange, N. J.

"The Pathological Aspect of Phimosis in Children," by C. N. Dixon-Jones, Brooklyn.

"Tetanus Neonatorum," by B. A. Waddington, Salem, N. J.

"The Prophylaxis and Treatment of Diphtheria," by J. Lewis Smith, New York.

"The Present Status of our Knowledge (including bacterial demonstrations) upon the Subject of Sterilized Milk," by Henry Koplik, New York.

"Cervical Adenitis," by B. T. Shimwell, Philadelphia.

"Sympathetic Convulsions in Children," by S. J. Radcliffe, Washington, D. C.

"Report of 30 cases of Diphtheria Treated by Sub-membraneous Injections, with Demonstration of Instruments," by A. Seibert, New York.

"Necrosis of the Maxilla, with a Report of three Cases," by Walter B. Johnson, Paterson, N. J.

"Annus Pediatricus MDCCCXC," by Wm. Perry Watson, Jersey City, N. J.

"Remarks on the Child's Ear" by Samuel Sexton, New York.

"The Chemistry and Clinical Value of Sterilized Milk," by Professor A. R. Leeds and E. P. Davis, Philadelphia, Pa.

W. PERRY WATSON, Chairman, Jersey City N. J.

HOBART A. HARE, Secretary, Philadelphia, Pa.

Section of Dental and Oral Surgery.

Address of the Chairman of Section, by Eugene S. Talbot.

"Alveoloid Growth," by W. H. Atkinson.

"Treatment of Fractures of the Maxilla," by Wm. Carr.

"Genesis of Contour Fillings," Illustrated by Geo. S. Allan.

"The Teeth of Invertebrate Animals," by A. H. Thompson.

"Some practical points on the care of Instruments," Wm. H. Potter.

"Rheumatic and Gouty Diathesis as Manifested in Diseases of the Peridental Membrane," by John S. Marshall.

"Dental Infirmary Patients,—The Use and Abuse of Dental Charity," by Richard Grady.

"Growth of the Cementum," by R. R. Andrews.

"Remarks on Incipient Necrosis and Caries," by J. Williams.

"Choice of Therapeutic Filling Materials," by W. W. Allport.

"Thorough Dentistry vs. Partial Dental Surgery," by J. Y. Crawford.

"Pathological Conditions produced by Galvanic action between dissimilar Metals in the Mouth," by George W. Whitefield.

"Care of the Teeth," by J. Taft.

E. S. TALBOT, Chairman, Chicago, Ill.

HENRY W. MORGAN, Secretary, Nashville, Tenn.

Section of Neurology and Medical Jurisprudence.

Address by the Chairman of the Section: "Early Psychical Symptoms of Traumatic Brain Injuries," by T. D. Crothers, Hartford, Conn.

"Psychological Social Problems," by Daniel Clark, Toronto, Canada.

"Status Epilepticus," by Gros R. Trowbridge, and Chas. B. Mayberry, Danville, Pa.

"The Neuroses from a Demographic Point of View," by Irving C. Rosse, Washington, D. C.

"The Functional Degeneracy of the Brain," by J. T. Searcy, Tuscaloosa, Ala.

"Diagnosis of Traumatic Lesions in the Cerebro-Spinal Axis and the Detection of Malingering Referred to this Centre," by B. A. Watson, Jersey City, N. J.

"A Consideration of Traumatic Lesions of the Spine Resulting from Railroad and Other Injuries; Their Immediate and Remote Results, Etiology, Pathology and Diagnosis," by Thos. H. Manley, New York, N. Y.

General discussion of "The Traumatic Neuroses with Especial Reference to Railway Injuries," to be opened by R. Harvey Reed, Mansfield, Ohio.

"Medico-Legal Investigation of Deaths by Violence in the State of Massachusetts," by Silas B. Presbury, Taunton, Mass.

"A Medico-Legal Study of Blood Corpuscles in Syphilis and Other Diseases," by Ephraim Cutter, New York, N. Y.

"On What Constitutes Reliable Evidence in Trials of Criminal Poisoning," by John Reese, Philadelphia, Pa.

"Hallucinations of the Sane," by David Inglis, Detroit, Mich.

"Personality as it Effects Inebriety," by T. L. Wright, Bellefontaine, O.

"Opium Inebriety, its Legal Recognition and Treatment," by W. S. Watson, Matteawan, N. Y.

PLACES OF MEETING OF THE ASSOCIATION AND SECTIONS.

The following is a list of places of meeting of the Association and Sections:

General Sessions, Albaugh's Opera House.
Practice of Medicine and Physiology, Grand Army Hall.
Obstetrics and Diseases of Women, Masonic Temple.
Surgery and Anatomy, National Rifles Armory.
State Medicine, Columbian University.
Ophthalmology, Medical Department University of Georgetown.
Laryngology and Otology, Medical Department University of Georgetown.
Diseases of Children, Masonic Temple.
Oral and Dental Surgery, Medical Department Columbian University.
Medical Jurisprudence and Neurology, Grand Army Hall.
Dermatology and Syphilography, Grand Army Hall.
Materia Medica and Pharmacy, Grand Army Hall.

HOTELS.

The following named hotels have liberally contributed to the funds collected by the Committee of Arrangements, and deserve the patronage of our members: Arlington Hotel, Ebbitt House, Welcker's Hotel, Willard's Hotel, La Normandie, The Arno, The Shoreham, The Randall, Metropolitan, Hamilton House, Hotel Johnson, Made's Hotel.

RAILROAD ARRANGEMENTS.

For railroad arrangements, etc., see advertisements pages 8, 11, 12 and 13.

SOCIETY PROCEEDINGS.

Omaha Medical Society.

The annual meeting of the Omaha Medical Society was held in the cafe of the Paxton hotel on the 14th inst. Officers were elected for the ensuing year as follows: President, Dr. B. F. Crummer; vice-president, Dr. D. C. Bryant; second vice-president, Dr. Harrold Gifford; secretary, Dr. J. P. Lord; treasurer, Dr. S. K. Spalding.

Dr. Charles Rosewater, who has acted as secretary the past year, asked to be relieved of the office, as the duties thereof had demanded more of his time than he could spare.

After the election the society listened to the reading of a paper on

SARCOMA OF THE CHOROID WITH TWO CASES.

by DR. D. C. BRYANT. The paper was discussed briefly by the other members of the society.

On motion of DR. GAPEN the delegates to the meeting of the American Medical Association, to be held at Washington, D. C., were instructed to invite the Association to meet in Omaha in 1892.

The Society also passed a resolution, offered by DR. GAPEN, protesting against the removal of THE JOURNAL OF THE AMERICAN MEDICAL AS-

OCIATION, from Chicago, from the latter city to Washington, as eastern physicians now contemplate migration. The secretary was instructed to send a copy of the resolutions to THE JOURNAL of the Association in Chicago.

SPECIAL CORRESPONDENCE.

Shall The Journal be Removed to Washington?

THE ACTION OF THE WAYNE CO., N. Y., MEDICAL SOCIETY.

To the Editors.—I send you a copy of the resolution passed, unanimously, by the Wayne Co. Medical Society at its quarterly meeting held today.

D. COLVIN, M.D.

Palmyra, Wayne Co., N. Y., April 12, 1891.

Resolved, That we deplore the agitation now going on relative to the removal of the office of publication of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, and we earnestly protest against any and every attempt to change the present locality of its publication.

A. A. YOUNG, M.D., Pres.
J. M. TURNER, M.D., Sec'y.

THE ACTION OF THE OMAHA MEDICAL SOCIETY.

To the Editors: At the meeting of the Omaha Medical Society held last Tuesday (April 14), the following resolution was passed unanimously:

Resolved, That the delegates from this Society to the American Medical Association be instructed to oppose the change of location of THE JOURNAL of the Association, and that a copy of this resolution be sent to THE JOURNAL.

C. ROSEWATER, M.D., Sec'y.

THE ACTION OF THE TENNESSEE STATE MEDICAL SOCIETY.

At the annual meeting of the Tennessee State Medical Society held at Nashville, Tenn., April 14, the following resolutions were *unanimously* adopted:

WHEREAS, There is now an effort being made in some quarters to remove THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION from its present commodious, comfortable, and successful location at Chicago to an untried field at Washington; and

WHEREAS, We consider the matter an unwarranted venture, as we can neither see nor conceive of any valid reason for such a change; therefore be it

Resolved, That we, the Tennessee State Medical Society, do hereby enter our most hearty protest against the proposed change, and respectfully request the delegates who may be appointed from this body to use their every endeavor to prevent the consummation of so hazardous an experiment.

Resolved, also, That the Secretary of this Society be requested to forward to the Editor of THE JOURNAL the foregoing preamble and resolution.

W. K. SHEPPARD, M.D.,
J. W. PENN, M.D., Pres.
D. H. NELSON, M.D., Sec'y.

THE ACTION OF THE HUNTINGDON COUNTY, PA., MEDICAL SOCIETY.

At the annual meeting of the Huntingdon County Medical Society, held at Huntingdon, Pa., on April 14, 1891, the following resolution was unanimously adopted:

Resolved. That it is the opinion of the Huntingdon County Medical Society that the office of publication of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION should not be removed from Chicago, Illinois, and that the delegates to the American Medical Association from the Huntingdon County Medical Society, of the State of Pennsylvania, are hereby instructed to vote against the removal of the office of publication. Attest,

GEO. C. BORST, Sec.

To the Editor:—By all means let THE JOURNAL remain at Chicago. It is a more central city. Washington is not the place for it.

FRANK D. GREEN, M.D.

Dallas, Tex.

NECROLOGY.

DR. JOSEPH H. WARREN, of Boston, died March 26, aged sixty. His father was the seventh son of General Warren, of Revolutionary fame. He was a medical director in General Casey's division, and of provisional troops during the last war as well as President Lincoln's medical attendant. He saw active service in the field before Yorktown, Va., and soon after was disabled while bearing special dispatches to Washington, and was obliged to resign. He was quite a traveler, traveled for health and pleasure, more than once serving as a delegate from the American Medical Association, of which he was vice-president in 1889 and 1890. He read papers before the British Medical Association and the French Academy of Medicine. He published in London a "Practical Treatise on Hernia," a second edition of which was issued in 1882 in America. He operated in Guy's Hospital, in London, and elsewhere, to demonstrate the method. He later published "A Plea for the Cure of Rupture," and has written very many monographs and medical papers, as well as general articles.

DR. LUTHER HALSEY GELICK, for nearly forty years a medical missionary to the islands of the Pacific, died at Springfield, Mass., on the 8th inst. His father was a missionary before him and brought up a family of seven, all of whom gave themselves to lives of self-denial in foreign lands. He was a graduate in medicine at the University of New York in 1850, and the following year went to Micronesia, with a pioneer party, destined there to spend twenty years. He was afterwards for many years a resident at Madrid, Spain. Nearly forty years of his life were passed in foreign lands.

MISCELLANY.

ROCKY MOUNTAIN MEDICAL ASSOCIATION.—The twentieth meeting of the Rocky Mountain Medical Association will be held in the parlors of the Arlington Hotel, Washington, D. C., on Wednesday evening, May 6, at 7:30 P. M.

JOHN MORRIS, M.D.,

Secretary.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from April 11, 1891, to April 17, 1891.

Major Passmore Middleton, Surgeon, granted six months' leave of absence on surgeon's certificate of disability. By direction of the Acting Secretary of War. Par. 4, S. O. 81, A. G. O., Hdqrs. of the Army, April 11, 1891.

Capt. Henry F. Birmingham, Assistant Surgeon, leave of absence granted S. O. 89, March 15, 1891, Dept. of the Columbia, is extended one month. By direction of the Acting Secretary of War. Par. 2, S. O. 81, A. G. O., Hdqrs. of the Army, Washington, April 10, 1891.

By direction of the Secretary of War, the following changes in the stations of medical officers are ordered: Capt. Marshall W. Wood, Asst. Surgeon, is relieved from duty at Ft. Meade, S. Dak., and will report in person to commanding officer, Ft. Preble, Me., for duty at that post, relieving Capt. William E. Davis, Asst. Surgeon. Capt. Davis, on being relieved by Capt. Wood, will report in person to the commanding officer, Ft. Clark, Tex., for duty at that station. Par. 11, S. O. 85, A. G. O., Washington, April 15, 1891. By direction of the Secretary of War, a board of medical officers, to consist of Major Henry McElderry, Surgeon; Capt. James C. Merrill, Asst. Surgeon; Capt. W. Fitzhugh Carter, Asst. Surgeon; is appointed to meet at West Point, N. Y., May 1, 1891, or as soon thereafter as practicable, to examine such cadets of the U. S. Military Academy as have been granted leave of absence until that date on account of physical disability, and to report upon their physical fitness to continue with the Corps of Cadets. Par. 2, S. O. 85, A. G. O., Washington, April 15, 1891.

Official List of Changes in the Medical Corps of the U. S. Navy, for the Week Ending April 15, 1891.

Medical Director Grove S. Beardsley, appointed a delegate to represent Medical Dept. of the Navy at meeting of American Medical Association at Washington, D. C., May 5.

Surgeon James M. Flint, appointed a delegate to represent Medical Dept. of the Navy at meeting of American Medical Association at Washington, D. C., May 5.

P. A. Surgeon S. H. Griffith, detached from the U. S. S. "Dolphin," and granted one month's leave of absence from date of detachment.

LECTURES.

THE CHEMICAL FACTORS IN THE
CAUSATION OF DISEASE.

A Course of Three Lectures delivered at the Post-Graduate Medical School of Chicago, March 2^d, 27 and 28, 1891.

BY VICTOR C. VAUGHAN, M.D., Ph.D.,
OF ANN ARBOR, MICH.

PROFESSOR OF HYGIENE AND PHYSIOLOGICAL CHEMISTRY AND DIRECTOR OF THE HYGIENIC LABORATORY IN MICHIGAN UNIVERSITY.

LECTURE I. GENERAL CONSIDERATIONS OF THE
RELATION OF BACTERIAL POISONS TO THE
INFECTIOUS DISEASES.

The majority of diseases may be grouped, from an etiological standpoint, into the following classes: 1. Traumatic; 2. Infectious; 3. Autogenous, and 4. Neurotic. It must be understood, however, that in many diseases the cause is not single, but multiple, and for this reason sharp lines of classification cannot be drawn. For instance, the greatest danger in those traumatic affections in which the traumatism itself does not cause death, lies in infection. The wound has simply provided a suitable point of entrance for the infecting agent. Indeed, the break in the continuity of tissue may be so slight that it is of import and danger only on account of the coincident infection. This is true in many cases of tetanus. Furthermore, an infectious disease, whether it originates in a traumatism or not, is markedly influenced by what we are pleased to call the idiosyncrasy of the patient, and by which we mean the peculiarities of tissue metabolism taking place in the individual at the time. A dozen men may be exposed alike to the same infection, and the infecting agent may find a suitable soil for its growth and development in two of these, while in the other ten this same agent meets with such adverse influences that it dies without producing any appreciable effect; or all may be infected, but with differences in degree, as is evidenced by variations in symptoms, in the length of time that the infecting agent continues to grow and develop in the body, and in the ultimate result. Every physician who has had experience in the treatment of typhoid fever, diphtheria, scarlet fever—or, in short, of any of the infectious diseases, will appreciate the importance of the personal equation

in his patients. That some neurotic affections originate in traumatism we know. That others of this class are largely due to malnutrition accompanied by improper metabolism or insufficient elimination; or, in other words, are to some extent autogenous, all believe. Understanding, then, that the above classification does not attempt a sharp and marked differentiation of the causes of disease, I wish to devote the first two of the three lectures, which you have kindly asked me to give, to a consideration of the chemical factors in the causation of the infectious, and of the traumatic, autogenous and neurotic diseases in so far as these are influenced by infection.

The science of bacteriology is now entering upon a new and promising era in its development. Heretofore, this science has been largely founded upon morphological studies. Bacteriologists have given their time and attention to the discovery of bacterial forms in the diseased organism, and to the observation of characteristics in structure and growth of different species of bacterial life. The question, do certain germs have a causal relation to certain diseases? having been settled in the affirmative, the next question which naturally arises is, In what way is this causal effect accomplished? How do germs prove harmful? To this question, a number of answers have been proposed. But as I have elsewhere¹ discussed these theories, I will not repeat them here. Suffice it to say that it is now generally admitted that the deleterious effects wrought by germs are due to chemical poisons elaborated by them during their growth. Granting this, it will be at once seen that the morphological study of germs, important as it is, becomes wholly inadequate in ascertaining their true relationship to the diseases with which they are associated. We must now study the physiology and the chemistry of germs, and until this is done we must remain ignorant of the true cause of disease, and so long as we remain ignorant of the cause, it cannot be expected that we shall discover scientific and successful methods of treatment. Suppose that our knowledge of the yeast plant was limited to its form and method of growth, of how little practical importance this knowledge would be. That the yeast plant requires a saccharine soil before it can grow, and that given such a soil

¹ Ptomaines and Leucomaines.

it produces carbonic acid gas and alcohol, are the most important and practical facts which have been ascertained in its study. Likewise, the conditions under which pathogenic germs multiply and the products which they elaborate in their multiplication must be ascertained before their true relationship to disease can be understood.

In saying that the morphological work upon which the science of bacteriology rests almost wholly is inadequate, I wish that it may be plainly understood that I am not offering any hostile criticism upon the great men who have done this work and who have formulated conclusions therefrom. The development of bacteriology has been in accordance with the natural laws governing the growth of all the biological sciences. The study of form naturally and necessarily precedes the study of function. The ornithologist finds a new species of bird. He first studies its shape and size, the color of its plumage, the form of its beak, the number and arrangement of the feathers of the tail and wing, the color of the eyes, etc. All this he can do with a single specimen, recognizing the fact, however, that variations, more or less marked, are likely to be found in other individuals. More time and wider opportunities of observation will be needed before he can tell where and when this bird is accustomed to build its nest, upon what insects, grains and berries, it feeds, with what other species of birds it lives in peace and with what it is at war. A much greater range of observation and study is necessary before the naturalist can tell how his newly discovered species would thrive if carried to a new climate, where it would be compelled to live upon unaccustomed food, to build its nest of strange material and to encounter new foes. I repeat that it is no discredit to the science nor to the men who have developed it, to say that the study of bacteriology has hitherto been almost wholly morphological; without the morphologist, the physiologist and the physiological chemist would not exist. The science having had for its support only morphological studies, the deductions and formulated statements arrived at by its students have been reached in accordance with the knowledge obtained from this source. But now, it being admitted that the causal relation between a given germ and a certain disease is dependent upon the chemical products of the growth of the germ, the fundamental lines of work must be altered in order to correspond with this new knowledge. Let us inquire into the changes, which the introduction of this new factor must make in our fundamental conceptions of the causal relation between germs and disease.

The four rules of Koch have been generally conceded to be sufficient to show that a given germ is the *sole* and sufficient cause of the disease with which that germ is associated. Briefly these rules are as follows:

1. The germ must be found in all cases of this disease.

2. The germ must be separated from other organisms and from all other matter found with it in the diseased animal.

3. The special bacterium thus freed from all foreign matter must, when properly introduced, produce the disease in healthy animals.

4. The microorganism must be found properly distributed in the animal in which the disease has been induced.

Let us give our special attention to the first of these rules for a few moments. What is meant by the statement that the special germ must be found in every case of the disease? How will A, pursuing his studies on the bacteriology of a given disease in America, decide whether or not a bacillus, which he finds, is identical with one which has been reported as invariably present in the same disease, by B, who has investigated an epidemic in Germany? What means are relied upon to prove the identity of these two organisms? The means which have been relied upon wholly are the form, size, reaction with staining reagents, manner of growth on the various nutrient media, and, in exceptional instances, correspondence in their effects upon the lower animals. In other words, with the exception of those instances in which the effects upon animals are tried, the characteristic, by which the germ causes the disease, is left wholly out of consideration.

Indeed, some of the most eminent bacteriologists have taught that in the identification of germs the reactions with staining agents and the appearances of the growths on the various nutritive media are of more importance than the observation of the effects upon animals. Thus, Flügge says:

"Inoculation experiments with both typhoid dejections and pure cultures of the Eberth bacillus have universally been without success. The few experiments in which a typhoid disease has followed inoculation or feeding have been made with impure material containing other active bacteria. It is known that a group of widely distributed organisms, which, however, are wholly different from the typhoid bacillus, have the power when injected subcutaneously or intravenously, of producing in animals death with marked swelling and ulceration of Peyer's patches. To these organisms undoubtedly are due the apparently positive results which some authors have supposed to be due to inoculation with the typhoid bacillus."

In other words, this eminent author teaches that although other germs may cause the essential symptoms and lesions of typhoid fever in the lower animals, they are not related to the germ found in the spleen of man after death from typhoid fever, because they do not react in the same manner with the aniline stains.

Bacteria cannot be classified so far as their causal relationship to diseases is concerned (and this is the most important knowledge to be gained from them) until we know the nature of the chemical poisons which they elaborate, for it is

by virtue of these poisons that they have any causal relationship to disease.

It is possible that two germs may be unlike in form, and yet they may produce poisons which are identical or those which are very similar in their effects upon man. One germ may be stained by Gram's method and another fail to be acted upon when so treated, but this does not prove that their chemical products are totally unlike.

We will suppose that in an epidemic of diphtheria A examines the membrane from a hundred, or we might as well suppose, a thousand children and finds a characteristic, well-marked, easily recognized bacillus in all. He isolates this organism and obtains it in pure culture. He inoculates animals and these manifest all the signs together with the appearance of the characteristic membrane of diphtheria, and in these animals he finds his bacillus growing as in the throats of the children. All of the rules of Koch have been complied with. Has A demonstrated that his bacillus is the *sole* cause of diphtheria? No. He has shown that his bacillus is *a* cause of diphtheria, but he has not proven that there may not be other germs, wholly different from his in form and size, which may also cause diphtheria. The most which can be proven by Koch's rules is that a given germ is *a* cause of the disease. They do not show, as most bacteriologists would have us believe, that this germ is the *sole* cause of the disease.

To illustrate, we will suppose that a botanist in visiting Arabia should find a tree producing a berry, the coffee berry, which when properly prepared and taken into the system produces certain effects. These effects are due to the alkaloid caffeine, and our supposed discoverer finds that they invariably follow the drinking of a decoction of these berries. Would he be justified in concluding that the coffee-tree is the only plant in the world capable of producing these supposed characteristic effects? Should he reach such a conclusion, the fact that it is not warranted would be shown by a study of the tea-plant in China and the guarana of South America.

What is meant in the first of Koch's rules by the statement that the germ must be present in all cases of the disease? In answering this question I will give two specific illustrations showing the manner in which eminent bacteriologists have applied this rule. This is well shown in the bacteriological literature of typhoid fever and diphtheria.

Eberth found the bacillus, which is now generally considered by bacteriologists as the sole cause of typhoid fever, in eighteen out of forty cases. In the examination of twenty-eight bodies dead from typhoid fever Gafky found the Eberth germ in twenty-six; Fränkel and Simmonds reported in twenty-five out of twenty-nine cases; Seitz in twenty-two out of twenty-four; Rietsch in thirty-

five out of thirty-six; and Kowal-ski found it present in each of twenty-nine cases. From these and similar reports bacteriologists have concluded that this germ is not only *a* cause, but the *sole* cause of typhoid fever. Are they justified scientifically in this conclusion? Have they any right to say that there is no other germ in existence which may cause typhoid fever? The speaker has shown that there are at least two other germs which induce the same symptoms in a more intensified form in the lower animals, and has isolated and studied the chemical poisons of these germs, and recently Babes has shown that in the examination of twelve persons who died at Bucharest of typhoid the Eberth germ was not present, and that an organism giving quite different reactions was present.

Löffler and other German investigators have shown the presence of a bacillus in the majority, not in all, of the cases of diphtheria which they have studied and they again conclude that this bacillus is not only *a* cause, but the *sole* cause of the disease. In a large number of cases in New York, Prudden failed to find the Löffler bacillus, but did find a wholly different organism. No one acquainted with Prudden's work will question the accuracy and care with which it was done. It is true that the chemical poisons of the Löffler bacillus have been studied, and no one can doubt that it is a cause of diphtheria, but it may be found that the streptococcus of Prudden is capable of elaborating a similar poison.

The moment that it is granted that the real poison of the disease is chemical in character, it becomes evident that no one is justified in saying that one germ is the sole source of such a poison. Such a statement would be as much unwarranted as one that the coffee-tree is the sole source of caffeine, or that the *strychnos ignatii* is the only species of the natural order *loganiaceæ* which produces a convulsive poison. In other words, the specific cause of a given disease is not to be determined wholly by the morphology of the germ found associated with that disease in a given epidemic, but by the character of the chemical poison which is the true *materies morbi*.

I think that we are justified in concluding that in those diseases in which the four rules of Koch have been complied with, the germ is *a* cause of the disease, but our range of observation must be much wider than it now is, before we can say that the given germ is the *only* cause of the disease. *It may be found, and I think this highly probable, that those few infectious diseases, such as anthrax and tuberculosis, which have such well-marked typical clinical histories, are due to equally well-marked and morphologically distinct microorganisms which can be recognized by microscopical study alone; but I do not expect that this will prove to be true in diseases showing such wide variations in symptoms as is done by typhoid fever and cholera infantum. In*

fact I am convinced that these last mentioned diseases may and do result from any one of a number of bacteria which are in form, size, methods of growth and reactions towards staining reagents, quite distinct one from the other, but which produce poisons similar in their effects.

That you may be convinced of the truth of the foregoing statements I give a few specific instances which will confirm them, and demonstrate that in their causal relation to disease, germs cannot be classified from a study of the form, size, methods of growth and reactions with staining reagents.

Typhoid Fever.—Eberth lays special stress upon the fact that his germ does not take the ordinary stains readily, and says that it is not colored by Bismark-brown and hæmotoxylin, and only slightly by the other ordinary stains; but what is the verdict of others on this point? In the paper in which he calls attention to the fact that he has photographed the short bacillus before Eberth had published his discovery, Koch says: "Eberth states that these short bacilli have but slight tendency to take stains. The photograph here given shows, to the contrary, that in taking stains these bacilli are but slightly inferior to other bacteria." Gaffky states that the best coloring agent is methylen-blue, but that the bacilli are stained very well with methyl-violet, gentian-violet, Bismark-brown and fuchsin, and less well by hæmotoxylin. Coats had no difficulty in staining with Bismark-brown. Meyer had the same difficulty as Eberth in staining; but Friedlander found that the bacilli in sections from the spleen stained intensely. In view of this variety of statement, can any one claim that these men were working with a germ which can be distinguished from others by its tinctorial properties?

Tetanus.—The tetanus germ of Kitasato and that of Tizzoni and Cattani are known to be quite distinct. Cultures of the former in bouillon are virulent, while those of the latter in the same medium are inert. Not only are these two organisms morphologically and biologically different, but their poisons are chemically unlike. Brieger and Fränkel precipitated the poisonous albumin of the germ of Kitasato with alcohol, but this reagent renders the poison of the Italian germ inert. Notwithstanding this difference, however, both microorganisms and their chemical products produce tetanic convulsions and death in the lower animals. We must, therefore, admit that there are at least two distinct germs, each of which is capable of causing tetanus, and how many other bacteria with like properties there may be no one can tell.

The Summer Diarrhoeas of Infancy.—In this class of diseases all attempts to find a morphologically specific germ have failed. The labors of Booker in this country, and of Escherich in Germany, have shown that no one species or variety is constantly present. No less than thirty dis-

tinnet germs have been obtained from the bowels and feces of children suffering from the summer diarrhoeas. A germ which is frequently present one season will not be found at all the next. Are we to conclude from this failure to comply with the first of Koch's rules that the summer diarrhoeas of infancy are not due to microorganisms? Certainly not; especially in view of the fact that Baginsky and Stadthagen have shown that the bacillus discovered by Baginsky produces a chemical poison which induces diarrhoea in the lower animals, and I have shown that at least three of Booker's bacteria produce poisons which have similar effects. To the contrary, we are justified in concluding that the diarrhoea may be due to any one or more of a number of germs which differ from one another sufficiently morphologically to be classified as distinct species. The similarity among these bacteria will not be discovered by a study of their size, form and reactions with staining reagents, but by a study of their chemical poisons, the agents by virtue of which they cause the disease. At the meeting of the American Medical Association at Newport, in 1889, I proposed, in a paper on the etiology of typhoid fever, that in those cases in which the lower animals are not available on account of their insusceptibility, before a given germ can be considered a cause of a disease, it must be shown that that germ can produce chemical poisons which will induce in the lower animals in an acute form the characteristic symptoms of the disease. That this rule would be a wise one I have become, even more strongly than I was at that time, convinced.

In the little volume on "Ptomaines and Leucomaines," written by Novy and myself and published in 1888, I gave the following definition of an infectious disease: "An infectious disease arises when a specific, pathogenic microorganism, having gained admittance to the body and having found the conditions favorable, grows and multiplies, and in so doing elaborates a chemical poison which induces its characteristic effects."

It should be remembered that this definition was written at a time when the importance of the chemical products of bacterial growth was not generally recognized. Indeed, at that time bacteriologists quite universally held to the mechanical interference theory, and more than a year later so good an authority as Welch, of Baltimore, stated that a knowledge of the chemical products of bacteria was interesting but not essential to a belief in the causative agency of a microorganism, and he went still further, inasmuch as he claimed that the successful inoculation of animals is not necessary in order to prove the causal relationship of a certain germ to a given disease. Now, it is generally conceded that a successful inoculation is a proof of the formation of deleterious chemical products, and in

case successful inoculation cannot be obtained on account of the insusceptibility of the lower animals, the demonstration of the elaboration of chemical poisons is deemed not only interesting but important. For instance, the strongest proof that the cholera bacillus of Koch has a causal relation to Asiatic cholera has been furnished by the study of its chemical products, and similar studies of many of the other infectious diseases have yielded results which are of both interest and importance, as I shall endeavor to show in the next lecture.

The only modification which I desire to make in the above definition of an infectious disease consists of an elaboration of what is meant by a "specific" microorganism. The specific nature of a germ is to be determined not by its size, form, growth on nutritive media and reactions with staining reagents, all of which properties are more or less variable with the conditions under which the germ has been grown, but upon its capability of producing within the body deleterious substances.

The study of the chemical factors in the causation of the infectious diseases opens up for us a field in which much work must be done. Let us attempt a statement of the nature of some of the researches that must be carried out along this line.

In the first place we must ascertain what germs are toxicogenic. This would necessitate a chemical study of all kinds of bacteria, both the pathogenic and the non-pathogenic. Every fact learned in this investigation will not have its practical application in medicine, but will have its scientific value, and many will most probably be of more or less direct service to man. There is a vast field here for careful scientific work, and I should be glad to see these researches carried out largely in our own country.

Secondly, it must be determined under what conditions these germs are toxicogenic. It is not at all probable that all those bacteria which are capable of producing poisons when grown on dead material outside of the body are also capable of multiplication and the production of the same substances when under the influence of the various secretions of the body. Some bacteria are destroyed by a normal gastric juice within a short time, while others are not. The conditions of life and growth are different when the infecting agent is introduced into the blood from what they are when infection occurs by the way of the alimentary canal. This is well recognized in the two forms of anthrax, one of which arises from inoculation through a wound and the other by way of the intestines. A preventive treatment which is efficient in the one is of no service in the other. Then again, we are to study those conditions of the blood and other fluids of the body, which are especially unfavorable to the successful

implantation or the continued existence of an infectious disease.

Thirdly, the chemical properties and the physiological action of these poisons will demand careful attention. Some are especially depressing in their action upon the heart, others seem to manifest their energy upon the central nervous system, while others still act like true gastro-intestinal irritants. In the study of the toxicological effects of these bacterial poisons every method of investigation known in the most advanced physiological work must be employed. The action of these agents on the heart, the brain, the spinal cord, etc., must be thoroughly studied.

After all this has been done we shall certainly advance in our knowledge of the treatment of the infectious diseases. The morphological study of bacteriology has been of inestimable value to us in the prevention of the infectious diseases. It has rendered the investigation of disinfectants both possible and imperative, and by the knowledge thus gained yellow fever has repeatedly, and Asiatic cholera in one instance at least, been kept from our shores. Epidemics of small-pox, diphtheria and scarlet fever have been arrested. In this way scientific medicine has been advanced, and such an advance is never made without great benefit to mankind in general. Moreover, antiseptic surgery, which had already been inaugurated by the genius of Lister, has received the scientific support which was necessary to its constant, universal and correct employment. All of these benefits, and possibly more, which do not occur to me at this time, have been accomplished, and to Pasteur, Koch and the host of others who have rendered this possible, we should be and are grateful. But what can those of us who are engaged in the treatment of the infectious diseases say of the present condition of the practice of medicine? As one of this number I am forced to admit that my successes are few and my failures many. Are we satisfied with the treatment which we now employ for tuberculosis, diphtheria, scarlet fever, typhoid fever and the other internal infectious diseases? Do we treat these diseases with much more success than our fathers did? They prescribed for their consumptive patient liberal food, cod-liver oil and all the open air exercise possible. They never carried a Bergeron hydrogen-sulphide bag, used a Weigert hot air oven, or injected Koch's lymph; but can we say that our successes are markedly more numerous than theirs? Has the knowledge of germs aided us in the treatment of these diseases? Do we today possess one germicidal agent which will destroy the bacilli of typhoid fever in the spleen of our patient and at the same time do no injury to the patient himself?

For myself I am perfectly willing to acknowledge that I am not satisfied with my success in the treatment of the infectious diseases, and it

seems to me that careful scientific study along the lines which we have been following to-night holds out sufficient encouragement to lead us to further study. Could we treat morphine poisoning before we knew anything of the chemical properties or the physiological and toxicological effects of this alkaloid? Can we counteract or antidote the typhoid poison, before we know anything of its nature or its manner of action? I do not mean to imply that it is the duty of each of us to become a chemist or to undertake physiological research. We need as much as anything else a closer study of these subjects at the bedside. The scientific methods of the laboratory should be carried into the wards of the hospital. The physiologist keeps the dog upon which he is making some important study under his own trained eye and trusts no one else with the observations. The patient with typhoid fever in the hospital ward is seen by his medical attendant once or twice during the day. The remainder of the time all observations must be made and records taken by a nurse, who is not only devoid of scientific training, but has so much work to do that but little time can be given to the individual patient. There is work enough in the study of the poisons of disease to employ the chemist, physiologist and clinician, and the greatest good can be secured only by the combined labors of all.

You may think it strange that, enthusiastic as I am about the importance of the study of the bacterial poisons, I have said nothing about the therapeutical uses to which some of them may be put, as evidenced by the introduction by Koch of his so-called lymph or tuberculin as a cure for tuberculosis. There may be valuable curative agents discovered among the products of bacterial activity, but I have never believed that a disease will be cured by the administration of the very poison which is causing the disease. I say I have never believed this, but I am open to conviction on this point, and take much interest in a study of the results now being reported from all parts of the world, as well as in my own observation of the effects of the proposed cure. So far, however, I have seen no sufficient reason for any change in my belief on this point.

(To be continued.)

A PORTRAIT OF VIRCHOW.—The famous portrait painter Franz Lenbach of Munich is painting a portrait of Virchow for the Berlin Medical Society. It will be unveiled at a festal meeting of the Society, and presented to the Langenbeck House. There it will hang beside a portrait of Langenbeck in the hall destined for the meetings of the medical societies of Berlin, for congress assemblies, festal ceremonies, etc.

ORIGINAL ARTICLES.

THE EFFECT OF ARTERIO-SCLEROSIS UPON THE CENTRAL NERVOUS SYSTEM.

Read before the Clinical Society of Maryland, January 16, 1901.

BY GEORGE J. PRESTON, M.D.,

PROFESSOR OF PHYSIOLOGY AND DISEASES OF THE NERVOUS SYSTEM, COLLEGE OF PHYSICIANS AND SURGEONS, BALTIMORE.

In order to appreciate fully the significance of disease of the blood vessels of the central nervous system, it is necessary to keep in mind the general plan of the blood supply of the brain and cord. If we disregard a few meningeal branches from other arteries, the brain is supplied by four trunks: the two internal carotids and the two vertebrals. It is not necessary to mention the well known arrangement of these arteries at the base of the brain into the circle of Willis. The blood-vessels that supply the brain are peculiar for their long and tortuous course through bony canals, and the fact that they are unaccompanied by veins. After having formed the circle of Willis they send branches to supply the different regions of the cortex, and other branches which penetrate the substance of the brain and supply internal parts. These latter branches while they are small are very important, because they supply the basal ganglia and internal capsule. They do not communicate with each other or with the cortical system of vessels and hence are known as end arteries, or what is a better designation, as terminal arteries. The term, end artery, is not a very good one, as confusion may sometimes arise between this and the pathological term, endarteritis.

The branches which supply the cortex are perhaps to a certain extent terminal arteries, though anastomoses of the larger branches take place in the *pia mater*. From these branches ramifying in the *pia mater*, arterioles pass into the cortex perpendicularly to the convolutions. These arterioles may be divided into two groups. The short or nutrient arterioles which form a network in the gray matter of the cortex, and the long or medullary arterioles which pass deep down into the white matter with little or no communication with each other, with the short arteries or the basal branches.

The significance of this peculiar mode of distribution of the arteries of the brain becomes at once apparent when we consider the effects of plugging by thrombus or embolus of a vessel which has no free anastomosis.

The spinal cord derives its blood supply from the vertebral, intercostal, lumbar and sacral arteries. Each vertebral gives off a branch, which branches unite and form the anterior spinal artery which runs in the anterior median fissure the

whole length of the cord. From this artery branches pass deeply into the fissure and along the anterior nerve roots. The branches which penetrate the fissure pass on into the gray matter of the anterior horns, where they form a rich network. The vertebrals also give off posterior spinal arteries which do not unite as do the anterior vessels, but pass down the posterior aspect of the cord, one on either side, near the attachments of the posterior nerve roots; these branches are united however, by numerous anastomoses, and send small twigs towards the posterior median fissure. From the periphery of the cord numerous branches pass into its substance, some of them reaching the gray matter. James Ross has shown that the arteries which supply the different areas of the cord are fairly constant and regular in their distribution.

The minute anatomy of the blood vessels of the central nervous system presents certain important peculiarities. The vessels are not as closely applied to the tissue in which they ramify as are the vessels in many other parts of the body, but lie in little canals known as the peri-vascular spaces. Most histologists agree that these spaces are lined by a delicate membrane, and communicate with the spaces in which lie the cells. They are undoubtedly lymph spaces, containing lymph corpuscles, and form the only lymphatic system really that the central nervous system possesses. If we examine a fresh or carefully prepared section of the brain we find that the structure of the arteries differs somewhat from the structure of the arteries elsewhere in the body. The coats are in the main the same, but between the *muscularis* and *adventitia* we find a space known as the adventitial space. The two coats are not in actual contact. This space may be regarded as a lymph channel. The veins possess a somewhat similar arrangement.

It was formerly supposed that arterio sclerosis, and particularly its later stage, atheroma was not of common occurrence in the arteries of the central nervous system. More recent investigation, however, has shown that this condition is frequently met with. It is to be noted, however, that one may fail to find any marked changes in the blood vessels of the brain and cord of subjects in whom there existed marked sclerosis elsewhere, and the contrary is perhaps sometimes seen, namely atheroma occurring in the vessels of the brain and cord while it is absent or not well marked in the general arterial system. The alteration in structure of the vessels of the brain and cord, affected with sclerosis does not differ materially from that found in the vessels elsewhere, and which was so clearly described by Dr. Welch at a former meeting of this Society. The fact that the vessels of the central nervous system lie in lymph spaces and are not supported by the surrounding tissue, and also the fact of

the space which exists between the *media* and *adventitia*, the adventitial space to which attention has been directed, offers special facilities for these vessels to alter their shape and become tortuous under high pressure, and greatly favors the formation of aneurism. The basal arteries and the large branches derived from them present thickenings, tortuosities, dilatations, aneurisms, and the microscopic changes which are familiar. If a section of the brain be made, the small arteries can be seen sticking up like bristles, with gaping mouths. If the small sized twigs be gently pulled out they will often show the most remarkable tortuosities. Irregularities in the size of the vessels, dilatations and constrictions occurring at frequent intervals in the course of the same vessel are commonly met with. Where the branches are given off there is often a marked dilatation. Small aneurisms, both fusiform and saccular are frequent and characteristic. The mode of formation of these miliary aneurisms, and their bearing upon intracranial hemorrhage, has given rise to some difference of opinion. Charcot and Bouchard, who first drew attention to this curious and important phenomenon, thought that the aneurisms were the result of an arterio-sclerosis, which began as a peri arteritis. That is to say that the inflammatory process began outside the artery. Cornil and Ranvier held that the aneurisms were the results of an endarteritis and a peri arteritis combined. In all probability the disease begins in the cerebral arteries elsewhere by a degeneration of the middle coat, as has been shown by Thoma and others.

This condition of miliary aneurism is rarely met with in the spinal cord. Most authorities agree with Charcot in saying that this peculiar formation of small aneurisms in the vessels of the brain, is the underlying cause of most if not all cases of ordinary intracranial hemorrhage. It might perhaps seem to be stating the case too strongly to say that miliary aneurism is always to be found in apoplexy, but it certainly is the rule, though exceptions do occur. Whenever they have been systematically sought for in persons dying from hemorrhage of the brain, they have been found, in nearly all cases. It requires some care and a good deal of patient work to detect their presence at times, for while they may exist in one case in great numbers, another case will show perhaps only three or four after the most careful search. Then, as has been noted, we may have numerous miliary aneurisms, without marked atheroma of the vessels elsewhere. Twenty five per cent. of Charcot's cases in which miliary aneurism was marked in the cerebral vessels showed no condition of atheroma of the arteries generally. It is very possible, then, that observers, not noting any atheroma in other vessels, have not been led to look for it in the brain, and so the frequency of aneurism, and consequent-

ly of arterio-sclerosis, has been underestimated by some authorities. On the other hand, there may be marked atheroma of other arteries and no miliary aneurisms found in the brain. This was illustrated in a case recently examined, in which the aorta showed large plaques of atheroma, and yet the most careful investigation failed to reveal a single miliary aneurism.

Next in importance to the formation of aneurism comes the great tendency to the formation, in the diseased vessels, of thrombi and resulting emboli. The roughened, diseased *intima* offers the most favorable conditions for thrombus, and this liability is enhanced by the fact that we may have local disturbances of the circulation, as slowing of the blood stream by a constricted vessel. The significance of thrombosis of the cerebral vessels becomes at once apparent when we consider the fact already alluded to, that the arteries passing up from the large trunks at the base of the brain to the basal ganglia and internal capsule, as well as the cortical system, are for the most part terminal arteries, and hence plugging of these vessels means softening of the area of the brain to which they are distributed, since no provision exists for collateral circulation.

Another pathological condition which is met with in sclerosis of the arteries of the brain, and which has perhaps some clinical significance, is the great tortuosity and unequal calibre of the vessels. In following the course of the smaller arteries, under the microscope, observing now a marked dilatation, now a narrowing almost to obliteration, and everywhere tortuosity, one cannot help thinking that these marked changes in the lumen and direction of the vessel must produce decided irregularity in the blood supply of the area to which it is distributed. It must be borne in mind that many of the brain centres are in constant activity, and hence must have a regular and uninterrupted supply of blood.

When we come to consider the effect of arterio-sclerosis upon the spinal cord, we have far fewer data from which to draw conclusions than in the case of the brain. Miliary aneurisms of the vessels of the cord, while they have been found, are rare. Thrombosis and embolism sometimes occur, and hemorrhage is now and then met with which would seem to have been dependent upon disease of the vessels. It seems to me that we might with some show of plausibility attribute certain degenerative cord lesions to arterio-sclerosis: We have seen that the arteries of the cord are distributed with a certain degree of regularity to the different columns of fibres. Now in conditions of sclerosis of the columns of the cord we commonly meet with a very decided increase of the neuroglia or connective tissue element. Such outgrowth produces compression and subsequent degeneration of the nerve elements. Now it seems to me that we might suppose, without

forcing the facts too much, that the hyperplasia of connective tissue in the sclerosed vessels, extending into, or beginning in the *adventitia*, might encroach upon and compress the nerve elements, or set up a connective tissue outgrowth around the blood-vessel, which would extend into the substance of the cord. Again, it is supposable that in conditions of arterio-sclerosis the blood supply to the connective tissue elements of the cord, the neuroglia, being irregular or even markedly deficient, an irritation might be produced which might lead to outgrowth of connective tissue and consequent damage to the nerve elements proper. The causes usually assigned as the most important in the production of sclerosis of the columns of the cord, such as alcoholism, syphilis, exposure to cold and wet, over-exertion, great mental excitement and the like, are many of them just the factors which are the most potent in the production of arterio-fibrosis. There been no observations that I am aware of bearing upon this point, either for or against the theory proposed.

It must be borne in mind that we may have a condition in the veins similar to that found in the arteries. This point has been clearly brought out by Spillmann, of Nancy, quoting Thiebaut, Thoma, Huchard, Borel and others. Of course this fact has not as much significance in considering the effect of atheroma in the central nervous system as in other parts of the body, owing to the peculiar arrangement of the veins in the former case.

One fact strikes us with peculiar force when we consider the clinical bearing of arterio-sclerosis and atheroma, and that is that we must distinguish between the condition occurring in the young and in those in early middle life, and the same condition occurring in the old. In aged people it would seem to be a part of the general decay of the tissues. Add to the general tendency to fatty degeneration, an enfeebled circulation, and we have the conditions most favorable to the deposit of the lime salts. And yet the system seems to adapt itself so perfectly to the gradual change that we may have the most marked conditions of atheroma with no attending symptoms other than those incident upon old age. How far the general symptoms of senility may be due to this change in the blood-vessels it is not easy to say. That this condition of the blood-vessels, causing irregularities of the circulation and impairment of nutrition, is an important factor in the production of many of the symptoms of senility, is almost certain.

It is not in the aged, however, but in the individual in middle life who has grown old before his time, old in all but years, that we see most clearly the evil effects of atheroma. The tissues of this latter individual have not become accustomed to the changed condition of the blood vessels, and have not adapted themselves to the irregular or deficient blood supply.

The study of the effects of arterio-sclerosis on the central nervous system resolves itself into the study of, first, senility or physiological decay, a subject of great interest and wide range, and which can be touched upon only very lightly in this paper; secondly, the effects of atheroma in the middle aged; the study of premature old age, of age as a disease, and finally the predisposition to hemorrhage in the brain and cord of atheromatous subjects, and the possible effect of the condition upon certain chronic degenerations of the cord.

I have noted the symptoms in about fifty individuals at Bay View Asylum, in whom atheroma was more or less well-marked, and have been surprised to find what a very high degree of arterial deformity may exist without producing any very marked symptoms. The following summary from the careful tables which were kindly prepared for me by Dr. Sanger will illustrate this point.

	p.c.	
Total number of persons examined	50	
Age of youngest person examined	15	
Age of oldest person examined	72	
Average age of persons examined	47.8	
Number of males examined	3	6
Number of females examined	20	40
Number of blacks examined	17	34
Number of whites examined	33	66
Number showing specific history	28	56
Number showing non-specific history	22	44
Number showing uncertain history	20	40
Number of intemperate persons	28	56
Number of temperate persons	22	44
Number whose arteries present no sclerosis at wrists	15	30
Number whose arteries present slight sclerosis at wrists	21	42
Number whose arteries present marked sclerosis at wrists	15	30
Number whose temporal arteries are not marked	13	26
Number whose temporal arteries are slightly marked	28	56
Number whose temporal arteries are marked	12	24
Number in which heart lesions were found	10	20
Number in which albumen was found in urine	9	18
Number showing mental impairment	16	32
Number of hemiplegias	12	24

Of course it is not intended to draw any very definite conclusions from such a comparatively small number of cases, but they are simply used by way of illustration. The atrophy and actual loss of brain weight in old persons is perhaps due in part to the faulty blood supply, which is consequent upon atheroma. While one would hardly like to say that atheroma of the arteries is always present in old persons, still the great frequency with which it occurs, makes it a physiological rather than a pathological degeneration. It is to this decay, this alteration of the blood supply to the central nervous system, this lack of nutrition to the centers, that we must attribute the ordinary mental changes of old age. The blood supply to the centres is imperfect, causing perhaps alteration in the cells, innervation is enfeebled and all the mental processes are slow. Often we see something more than a mild decay of the mental faculties. The various forms of senile dementia, present pictures in which the physiological process of decay has been in part replaced by a more decided degeneration, a pathological process. We may have conditions of dementia with hypochondriacal delusions, with total loss

of memory, with almost entire abolition of the intellectual faculties, dependent largely if not entirely upon an atheromatous condition of the vessels and the changes in the brain incident upon such condition. It is not this state of gradual senile decay dependent though it is upon atheroma that especially engages our attention; it is this same condition of atheroma which has overstepped the physiological bounds. That is to say a condition of atheroma in persons whose age does not warrant such a change, or as noted above, symptoms other than those of mere senility, occurring in elderly people. In persons who are not yet old, but whose arteries are atheromatous, we often see very marked mental changes. The general disposition of the individual often undergoes some decided change: he becomes irritable, excitable, hysterical, or a condition of hypochondria with apathy supervenes. The mental symptoms peculiar to old age are intensified. The picture is not unlike that of beginning general paralysis before the advent of delusions. There is an inaptitude for any kind of mental exertion, and the memory becomes very bad. Such symptoms as these are frequently met with and are commonly ascribed to the effect of the diseased condition of other organs than the brain, notably to the effect of the lesion which often coexists in the kidney.

Bearing in mind the condition of the arteries in the brain, and the consequent derangement of the circulation, it is easy to conceive how such symptoms as these detailed are produced. The small arteries are often narrowed almost to the point of obliteration, and any increased vaso-constrictor action will temporarily close them.

One of the most pathognomonic symptoms of arterio-sclerosis of the vessels of the brain is transient paralysis. These attacks are sometimes very frequent and well marked. They come on with the suddenness of embolism, or again gradually like the formation of a thrombus, last from a few minutes to a few hours and are entirely recovered from. Such a person nearly always dies from hemorrhage or softening as the result of the rupture or permanent closure of the vessel. Due to the same cause, narrowing or temporary closure of the small arteries are severe headache and vertigo. This last symptom has been carefully investigated recently by Grasset who finds in addition to simple vertigo, epileptiform vertigo and attacks of syncope. The most important change, however, in the vessels is the formation of milary aneurisms, which has been described, for it is to this condition that most cases of simple apoplexy are due. Given this condition of milary aneurism, it is easy to see how with high arterial tension present the conditions for hemorrhage are most favorable. The fact that arterio-sclerosis is undoubtedly as has been shown, the underlying cause of milary aneurism, and also that the same condition favors the production of thrombosis and

embolism, gives the subject great importance.

The limits of this paper do not permit any discussion of the subjects of intracranial hæmorrhage and thrombosis and embolism. Miliary aneurism, as has been noted, is very infrequent in the vessels of the cord, and as non-traumatic hæmorrhage into the cord is a comparatively rare event, this fact might be adduced to strengthen the position taken, that these small aneurisms are always, practically, the precursors of hæmorrhage in the brain. Of course there are other reasons why hæmorrhages into the cord are infrequent, as the length, size and mode of distribution of the spinal vessels. It is doubtful whether any symptoms can be ascribed to changes in the blood-vessels of the cord, unless we include anemia and hyperemia, which can hardly be said to be conditions which can be recognized clinically.

The purely theoretical suggestion mentioned in the first part of this paper, that perhaps atrophy of the vessels of the cord may be a factor in the production of sclerotic degeneration of the fibres in the manner indicated, may, if confirmed by any facts, prove useful in clearing up our somewhat indistinct ideas of the production of these lesions.

There are, as we have seen, no very pathognomonic symptoms of arterio sclerosis of the vessels of the central nervous system. The diagnosis must rest upon the general symptoms that have been outlined. When a patient presents certain of these symptoms, and shows sclerosis of the vessels that can be examined, we can pronounce with some degree of certainty upon the probable condition of the arteries of the brain. The ophthalmoscope sometimes, though by no means always, shows us a condition of sclerosis in atrophy of the vessels of the retina. Raehlmann found changes in the vessels in forty-four out of ninety cases examined, or nearly fifty per cent. He describes a certain hazy appearance of the vessels, looking as if a thin veil were stretched over them. He noted dilatations and constrictions in the vessels and in two cases aneurism, and found the veins affected also, in twenty six per cent. of the cases.

One can say little as to treatment, other than the general rules that are laid down for the treatment of the general condition. It is necessary for patients who have a high degree of arterio-sclerosis to avoid violent sudden exertion for obvious reasons. At the same time systematic, regular exercise in the open air, with hill climbing in suitable cases, is of great value. Avoidance of excessive amounts of liquids is certainly an important point. Large quantities of water cannot but be injurious, by overfilling, or at least greatly increasing the total quantity of fluid in vessels that are already embarrassed. The diet should be light and nutritious. An occasional saline purge is beneficial, such as concentrated

magnesia sulph. The bromides are often of decided value in quieting the cerebral circulation, as are also warm baths. Nitro glycerine is frequently of value in these cases, especially when we have a sudden raising of arterial tension and the danger of intracranial hæmorrhage imminent. In these acute conditions an ice cap to the head is valuable.

The above imperfect sketch of arterio-sclerosis of the central nervous system will, I trust, aid in directing attention to the importance of the subject, and show the necessity of more careful clinical work to make the picture complete.

9 E. Townsend St.

REPORT ON THE OPHTHALMOSCOPIC EXAMINATION OF DR. PRESTON'S CASES OF ARTERIO-SCLEROSIS.

BY HARRY FRIEDENWALD, M.D.,
OF BALTIMORE, MD.

As a preface to the short report of the result of the ophthalmoscopic examination of Dr. Preston's cases, I should like to state that it is but recently that attention has been attracted to those changes of the retinal arteries as are found in general arterio-sclerosis. A few years ago Ole Bull¹ described several cases of disease in the retinal arteries, and showed how this was the cause of symptoms frequently ascribed to embolism. Raehlmann² made an exceedingly careful study of the relation between general and retinal arterio sclerosis, besides collecting a few scattered cases in literature. He examined ninety cases of general arterio sclerosis and found that in most cases the retinal arteries were narrow and tortuous, that 19 per cent. showed whitish margins along the retinal arteries, that 21 per cent. presented localized narrowings in their course, but that retinal aneurisms are very rare. Confining ourselves to these signs of arterial disease without considering the changes in the veins which he likewise frequently found, we must admit that the results are very remarkable. They are, indeed, surprising, if you remember that in all works on ophthalmoscopy such changes are not considered throughout; 6 per cent. referred to; that in the very latest, that of Gowers, we find the statement referring to general atrophy, that "in cases in which it is well marked elsewhere" he has "often looked for appearances in the retina suggesting its existence but without success." Prof. Hirschberg recently published the results of very careful ophthalmoscopic examinations of fifty persons between the ages of 60 and 80 years. Besides the many other "senile changes" he finds that 46 per cent. of the persons examined showed changes in the retinal arteries; 44 per

¹Ninth International Medical Congress Reports, Washington, Vol. III, p. 665.
²Zeitschrift f. Klin. Med., H. 5 and 6, Vol. XVI.

cent. of the persons examined showed variations in the caliber of the arteries at different points in their course; 2 per cent. showed whitish lines on their margins.

Before going further, it would be well to explain more definitely what is meant by these terms. The healthy retinal artery is perfectly transparent. What we see is the blood column within it. When the walls of the arteries thicken at the expense of their inner caliber and the thickened portion remains as transparent as the healthy vessel—and this is commonly the case—we detect the change in the narrowing of the column of blood. This thickening may take place at localized points, causing the localized variations in the thickness of the blood column or throughout the course of the vessel. In the cases mentioned above, we must, therefore, remember that the terms refer only to the blood column, and that we infer from these the condition of the vessel, for instance, when Kaehlmann describes "localized narrowings of the arteries," there are only localized narrowings of the blood column, and we infer from these that there are localized *thickenings of the walls of the vessel*. In those cases where "white lines are seen along the margins of the vessels," the wall of the vessel has lost part of its transparency, and reflects some light which is seen as the white lines. This depends upon a change in the substance of the vessel, or a deposit within it different from that in the transparent thickening mentioned above, and is much rarer.

My attention was first drawn to the localized narrowings (apparent!) of the retinal arteries in cases of optic nerve atrophy, and especially in those due to embolism of the central retinal artery, in which conditions they are much less uncommon than is ordinarily supposed. But their importance struck me when I saw them in a case of beginning *retinitis albuminurica* where the signs of inflammation were almost limited to but one eye, while the localized narrowings could be seen in the retinal arteries of both eyes. Since then I have paid more attention to this point and have found the changes not infrequently.

It was with great pleasure, therefore, that I undertook to examine the retinal arteries of Dr. Preston's cases. I must mention that some of the cases were in bed when I was at the asylum, and could not be examined sufficiently carefully with the ophthalmoscope to look for these minute changes. For this reason only twenty-nine cases were examined, or fifty-eight eyes. In eighteen of these eyes (in twelve patients) an ophthalmoscopic examination was rendered impossible by such impediments as cataract, corneal opacities, etc., and this reduced the number of retinæ examined to forty (in twenty-three patients).

Of these forty retinæ, nineteen presented decided local or general narrowing of the arteries with frequent tortuosity (twelve patients); ten presented moderate or slight changes of the same kind (seven patients); four presented whitish margins along the arteries (two patients); one presented a hæmorrhage on the papille; seven appeared thoroughly normal (five patients); two appeared thoroughly normal, while there were other extensive retinal changes. Besides these I noted in several cases senile retinal changes, in the characteristic little yellowish spots due to colloid degeneration of the lamina vitrea of the choroid.

The proportion of cases in which decided changes were found is so great that I am led to thoroughly accord with Kaehlmann as to the frequency of these changes and their importance in diagnosis.

A KNOWLEDGE OR A TIME REQUIREMENT. A PLEA FOR A MORE RATIONAL SYSTEM OF MEDICAL LEGISLATION.

BY YOUNG H. BOND, M.D.

CLINIC OF THE MARION SIMS COLLEGE OF MEDICINE
AT TULSA, OKLA.

The very general move in the direction of medical legislation during the past year or so, indicates the urgent demand on the part of the profession, for the just and proper regulation of the practice of medicine. In addition it is significant of the increase in competition and of the growing metamorphosis of the art of medicine into the science of medicine, of which the precepts and teachings follow such fixed laws, that he who studies may learn.

THE NINETEENTH CENTURY.

Our nineteenth century is a wonderful one—the like of which has never been seen in the whole compass of earthly years. Born during the great struggle of freedom against tyranny and oppression, living through the downfall of the ancient superstition of the divine right of Kings, it is about to make its exit from a world whose democracy is stamped in every act, and whose parting requiem to the hoary century will be "Vox populi, vox Dei." The people—the Demos rule. Throughout this whole century an equalizing power has been exerted which has been so thoroughly engrafted upon the lives and actions of men, that it has become the spirit and temper of the age.

Such a condition must have a positive bearing upon our civilization and its effects may be concentrated in the one expression, competition. Fair, open competition is the life of our institutions, but when it begets exclusion, it becomes the very bane of their existence.

Prof. Hirschberg published this case in detail. *Centralblatt f. Augenhe.* 1890, p. 200.

MECHANICS AND DOCTORS.

"Too many mechanics" is the cry, and forthwith in not a few branches of labor an elaborate system of restriction is practiced, and the number of artisans is maintained small by control of apprenticeship vested in the workers of that special line. As a consequence we find an undue limitation of the number of apprentices, and an equally undue extension of the time of apprenticeship, all because those within the inner circle fear honest competition.

What a decided similarity certain misdirected members of the medical profession would encourage between their high-aiming profession and these restricted divisions of labor. Do we not hear on all hands the cry, "Too many doctors, too many medical colleges, let both be limited." Again, like the apprentice-restricting mechanic, they say, "Make them study longer; make the restrictions greater" in face of the fact that they who rant and cry "reform" underwent the application of no such law, nor would. They cry, "The wolf! the wolf!" but fail to protect their charge by just and equitable safeguards, preferring, it appears, to resort to artificialities.

MEDICAL LEGISLATION.

It is a sad feature for our vaunted, fraternal and unselfish feeling for one another, that such an affair as medical legislation is necessary. Its origin, coeval with that of medicine, dates back to the time of Hippocrates, whose stringent oath formed at once an obligation and a text for future laws. Throughout the middle ages medical laws prevailed, though more or less crude. In these more modern times medical legislation is an element in every civilized set of laws, some natural and just, others artificial and presumptuous.

Our own country is at present in the throes of the subject and each State is prodded here and there, with persuasive prayers or emphatic demands, emanating not from the people but from the doctors. The consequence is that many legislators and the public look upon the medical profession as a band of sycophants, always boasting of their professional regard for one another, yet ever anxious to outdo each other, ever seeking protection, yet becoming the most violent and persistent of persecutors.

Is it strange, therefore, that sarcasm should now and then creep into our legislatures, such as, for instance, the bill introduced by a Missouri legislator, fixing the uniform rate of \$1.00 for visits and fifty cents for office consultations? Other bills of a like strain have been presented, a recent one being an act to compel each physician to advertise in the local papers his name, age, years of practice and source of medical diploma. All this is medical legislation.

Every time a State legislature meets there is a pilgrimage of doctors to the State Capitol, asking

that certain laws be enacted, the sum and substance of all being the lessening of competition and the exaltation of the few.

Some years ago the animus appeared directed towards the annihilation of quacks and impostors. Much good was accomplished, but the more the charlatans were persecuted, the more they prospered. And to-day, according to the provisions of the courts, the only restriction is "Thou shalt not lie." They may advertise what they will, so long as falsehood does not appear.

The people did not eventually look so kindly upon the efforts of the profession to efface quackery, not as has been so often represented, because of their desire to be humbugged, but because they knew there were two sides to every question, and because they felt certain that so notable an effect must have some deep-seated cause. Adding to this the great stampede of doctors for medical legislation, they arrived at the conclusion that doctors were perhaps actuated by selfish motives, just as much as by their interest in humanity, and they decided that opponents and prosecutors should not be made judges and executors. What was the result? We hear of the Board of Health being refused support year after year; in more than one case the board has been compelled to cease its prosecutions as a condition of its existence, and in one notable instance, the official member was compelled to resign in order that an appropriation might be made.

THE THREE COURSE REQUIREMENT.

The contest for a three-course qualification is far more in opposition to democratic principles than what has just been mentioned. The *raison d'être* of its advocacy by the profession is evident. Shuddering at the laxness of its conditions it seeks to improve itself. Commendable indeed, for there are many doctors who do not deserve the title and whose knowledge of medicine is confined to exceedingly narrow limits. Many are graduates who attended two courses, some three courses, others perhaps still more. I, too, agree that this is due to the fact that two years of attendance at a medical college has been the standard of license. But, believe me, I consider this the fault of the whole system and not of the lack of a three-term requirement.

If these doctors, if all doctors would have been examined by a Board, the number of ignoramuses would have been immeasurably less, in fact, it would be *nil*. What assurance have we that the adoption of a three-years course will change the existing order of things? Will the fact that three years are required make the professors any better as teachers or the students any more faithful? Will it not encourage laxness on the part of the teachers and idleness on the part of students? It is indeed plausible to consider that many students will spend their time after the fashion of so many

of their continental co-workers, whose time and money wax so heavy on their hands that they spend the half in riotous life and dissipation.

Of course if the instruction is improved coincidentally, and the examinations made more rigid and effective, in so far good will be accomplished. This is, however, by no means due to the lengthened course, but to the knowledge requirement which has been added.

THE KNOWLEDGE REQUIREMENT.

And here is just where I rest my oars, in the calm and righteous waters of knowledge. Knowledge the basis, knowledge the foundation, and knowledge the standard of qualification and excellence.

Make the two or three-course student pass a satisfactory examination before a competent board and you settle the question at once upon a basis both rational and just. No school's *ipse dixit* is taken; all submit to a fair and impartial test. Under this system a student who is a good chemist, on account of his academic education, needs not worry through two or three years of reiteration of what he already knows, and the capable druggist would be saved much time that otherwise he would squander in listening to lectures, useless to him. Equally would there be given to a nurse of experience or to one who has had much to do with invalids, the opportunity of deriving whatever benefits he deserves, and not be hampered by a time requirement, the same for tyros and for more experienced students.

With three courses a compulsory condition to graduation, a competent graduate of a good two-years school, whose professors have been conscientious, would be denied the right to practice and to exercise his hard-earned knowledge as he should, while the incompetent graduate of a three-term college of the most questionable reputation, would at once by the power and might of an unjust act, enter into the joys of the professional kingdom. Observe the whole system which should be an encouragement to industry and knowledge, by reason of the unnatural restriction of time, simmers down to an impalpable and foolish mixture of sentiment which is both unreal and ridiculous. Unreal because its basis is artificial and inefficient, and ridiculous because its application accomplishes but slight improvement at best, and that at the expense and hardship of injustice to the very men whose entrance into the profession is so desirable.

It is evident then that the three-term qualification places us no nearer the goal of our efforts than we are at present, for under its action, as now, the whole matter of licensing practitioners would rest in the hands of the professors of medical colleges—interested parties.—and not vested, as it should be, in the divine right of the people, in a board whose standard is knowledge and fairness to all.

Yet so long have doctors advocated the deification of time in this particular that what should be the foundation of medical legislation is overlooked, yea ignored, in the fetich worship of the time god.

This appears the more astonishing from the fact that the knowledge requirement is such a taking argument with legislators and men whose work and study is law-making. In the recent consideration, before the Missouri legislature, of the three-course measure, the bill was lost not, as has been falsely represented, by personal influence, but because the senators saw the fallacy of considering time and not knowledge as the proper requirement.

To say that every medical student shall attend for three years a medical college is to minimize the difference which exists between intellects and to deprive many a competent man from enjoying on account of a few paltry dollars, the fruits of his industry and knowledge, thus defeating the purpose and sense of all law.

I believe in trusts of no kind, and I most decidedly enter a protest against what is nilly-willy a medical students' trust. Any combination having for its avowed purpose a limitation based upon a standard which is unjust, which dictates unfairly and summarily, and which excludes deserving individuals from the enjoyment of such rights which by virtue of their knowledge they should have—when such a combination exists by agreement it must answer to the name of trust. As such it is detrimental to our country's interests and is in direct opposition to the old sterling principles of our government, that each man should receive fair treatment by the laws and that justice be given in accordance with each man's deserts.

FOREIGN DOCTORS.

Much has been said of the superiority of the European doctors over the American production, a statement whose deprecation is accompanied by the information that the fault is in the two-years' course. Again I beg to take issue for the palpable reason that the rigid examinations to which each student is subjected furnish proof which no argument as to time can belittle.

In Germany two examinations are held, the University and the State, each being independent of the other. It might be interesting to mention the number of rejections by the Prussian State Examiners of those who had already passed the University Examiners. In the year 1890 out of 563 applicants, 231, or 29.09, per cent. failed. Forty per cent. of the applying graduates of the University of Berlin were rejected. Where is the efficiency of the long term school compared with a good examining board? Certainly there is much valid argument in this little statement of the Prussian examinations.

In France the whole matter is left to the six Medical Faculties who constitute virtually six examining boards and who alone are authorized to issue diplomas to students of all the French schools.

In England, while the diploma issued by the University Faculties (in themselves almost equivalent to an impartial examining board) carries with it a licensing power, the various royal colleges make examinations granting to the successful applicant what is distinctive evidence of the knowledge he has acquired.

Austria and Russia have laws similar to Germany and hence present a proper solution to the question.

These illustrations are given to indicate as clearly as possible that the circumstance of the high intellectual standing of European physicians depends upon the constitution of what is equivalent to examining boards, and upon the strictness of the examinations, rather than upon the number of days, hours and minutes devoted to medical study.

It is a very serious question whether or not the unamerican legislation based upon a time requirement and excluding all who do not comply with its provisions is constitutional. Certain it is that the recent resolutions of the various boards of health which define the term "College in good standing" to signify a three-term school will not hold in any Court in the land. Efforts on the part of boards of health, such as has just been indicated, are valueless as they are misdirected. Any college which fulfils the significance of the term "College in good standing" at the time of the passage of the Act, can by mandamus compel the board to grant licenses to its graduates.

A more rational definition of the term, the boards might adopt, to-wit: Such colleges, all of whose students are able to pass a satisfactory examination before the boards of health. It does seem to me that this would be equally as legal and far more satisfactory and just.

OBJECTIONS TO A THREE-COURSE REQUIREMENT.

1. It possesses an erroneous basis, viz.: the standard of time and not of knowledge.

2. It is unfair in that it takes no cognizance of the superior intellectuality and industry of students.

3. It allows no credit for previous work and study, no matter how extensive, unless pursued regularly in a recognized medical school.

4. It is unjust because it works hardship upon deserving young men who happen to be poor in worldly goods; the rich are thus given the advantage and preference.

5. It perhaps would encourage laxness of teachers and indifference of students.

6. The ends would not be accomplished because second class colleges would exist under its en-

forcement just as well as now and they would be equally well patronized.

ADVANTAGES OF THE EXAMINING BOARD.

1. It possesses a just and rational basis, that of knowledge.

2. Every student would perforce depend upon his own efforts and zeal, and would not be indifferent of his studies unless he was not anxious to practice.

3. It is impartial—the rich have no advantage over the poor.

4. The licensing power being taken away from the medical colleges, their instruction, by the sheer force of competition, would be the drawing card for students would go where they could most easily graduate.

5. Second class colleges (and by this I mean those characterized by loose management and incompetent instruction) would be forced out of existence, because so many of their graduates would be rejected by the various State boards.

In conclusion let me restate a remark that I have already made, to the effect that it will be easy to convince the legislators of the wisdom of this measure; it is so thoroughly in keeping with fairness and right that to the law-makers it so smacks of the very essence of all law, that they advocate it in preference to all other measures.

Then let the right prevail; relieve the boards of health of the annoying duty as censors of the medical profession, and dictators of medical colleges; let the State's money be expended not for the compilation of statistics, their publication and circulation, of value to the doctors alone, but for the prime object of such a board—the hygiene of the State; let the impartial board of examiners pass on every new graduate who seeks the privilege of practicing in the State.

In such a commonwealth, the law of medicine be the law of fairness, democracy and right, and the licensed doctor will lie more comfortably on the bed of roses, nurtured by his own industry, and the incompetent one will seek some more congenial occupation.

Three results will obtain:

1. An ever increasing number of good, competent and worthy doctors.

2. An ever decreasing number of unworthy, unprofessional and incompetent physicians.

3. Medical colleges upon a higher, better and more intelligent plane.

Grand and Page Ave.

INCREASE IN THE USE OF ALCOHOLICS IN FRANCE.—From late returns it is found that the consumption of alcohol in France is largely increasing, and this despite the fact of the decrease in population. Can it be shown that there is a relation between these two processes?

ETIOLOGY OF ALCOHOLIC INEBRIETY.

Read before the American Association for the Study and Cure of Inebriety, April 11, 1891.

BY L. D. MASON, M.D.,

CONSULTING PHYSICIAN INEBRIATES' HOME, FORT HAMILTON, L. I.

The causes of alcoholic inebriety may be divided into *predisposing* and *exciting*, and the latter into two forms, *direct* and *indirect*. Inebriety from either of these latter subdivisions may be comprehended under one term, "acquired" inebriety—in contradistinction to those forms of inebriety directly traceable to heredity. This term "acquired" we shall apply to the form of inebriety due to "accidental" causes.

In the great majority of cases inebriety is not voluntarily acquired in the same sense that a person deliberately and as a matter of choice "makes himself an inebriate" so to speak, we use the term acquired, therefore, as we would apply it to other diseased conditions, not necessarily by its use implying a "moral delinquency." The *predisposing* cause of inebriety is latent and has to be called out by some exciting cause, either direct or indirect, usually of a *slighter* nature than would develop an "acquired inebriety."

Heredity is the great underlying or *predisposing cause* of alcoholic inebriety, in the same sense that heredity is the predisposing cause to many diseased conditions—as insanity, phthisis, gout, etc., constituting a diathesis or tendency to special diseases. We can with perfect propriety use the term "inebriate diathesis." We can trace "the pedigree of disease," as Jonathan Hutchinson calls it, in inebriety as in other forms of disease. Dr. Elam affirms that the offspring of the drunkard will inherit either the original vice or some of its countless protean forms. Plutarch, in his essay on "Delays of Divine Justice," asserts this fact; likewise Aristotle and Plato. "The fathers have eaten *sour grapes*, and the children's teeth are set on edge," writes the Hebrew prophet, and amid the thunders of Mount Sinai the finger of God wrote on tables of stone, "the sins of the father shall be visited upon the children."

Dr. Norman Kerr regards *maternal inebriety* as the chief hereditary cause of inebriety. Statistics show that female inebriates are much more common in Great Britain than with us—in Wales convicted inebriate females to convicted inebriate males stood as 3 to 1, while in the upper classes of English society it is well known that inebriety among females is greater than in America. My own observations trace the hereditary cause in the majority of our cases to an inebriate father.

Héritité croisé, or cross heredity, has been noticed in inherited inebriety—that is inebriate mothers gave rise to inebriate sons; inebriate fathers to inebriate daughters. Giron states that the hunters have a proverb, "*chienne et chien—chienne et chien*"—the mother's qualities

in the son, the father's in the daughter. Buffon recognizes that fact, also; personally I have not any observations to give on this point.

Alarism has been observed; that is, where the inebriate tendency or diathesis escaped the second generation and appeared in the third—the grandparents being the transgressors. We notice this fact in other diseases, as consumption, etc.

This is the sequence that is established should an inebriate mother conceive:

1. The fetus may die *in utero*. Miscarriage is a common condition in chronic alcoholism in pregnant women.

2. Should the fetus survive, pass to full term, and a living child be delivered, it may be an idiot or congenital imbecile.

3. Escaping from these conditions, and manifesting a fair amount of intelligence, the child, at or about puberty or earlier, may develop one of the various neuroses—chorea, paralysis, epilepsy, etc.

4. Passing from youth to manhood without any of these manifestations, then suddenly, oftentimes from slight exciting causes, inebriety, or insanity, stand out in bold relief, and the hand of fate, shall we call it? draws the curtain on a life that has struggled from birth with an "inebriate diathesis."

Surely no class of persons in this wide world have a more marked claim on our aid and sympathy than these "*miserables*." Impotent to help themselves; lacking entirely that necessary self-restraint and control that belongs to a healthy, normal constitution. The so-called moderate drinker—we define such a one as a person who drinks habitually every day, so as to keep himself moderately stimulated, and his blood and fluids moderately alcoholized, but is never drunk, never loses his self-control, and is eminently respectable in the general sense of that term. Such a man we assert may be the originator of a long line of inebriates, insane or neurotic individuals. It is a common impression that the bloated drunkard and the debauchee alone gave being to such a progeny, yet so potent, so far-reaching are the effects of alcohol it continuously used with so-called moderation, that who shall say in what quantity it may be used safely, habitually, so as not to affect cell growth in our own organism, and dwarf and degenerate it tenfold in the being whom we may beget. The modified cell in our own organism being much more modified in our progeny.

Dr. Baer, of Berlin, says:

"The extremely delicately organized, very sensitive and easily destroyed construction of the nerve and ganglion cells presupposes for the normal physiological function of this structure the completeness of integrity of this apparatus, not only anatomically, but also physio-chemically. *Every, even the smallest, invasion* on the nutritive and formative processes produces here a reaction of incomparably graver significance and weightier results than on any bodily tissue."

Dr. Baer refers to the brain particularly, for upon the brain and nervous system alcohol produces its most marked (probably functional) changes, and slight changes in cerebral or nerve tissue mean a great deal more than similar changes in other tissues or organs. We do not feel that we are making an extravagant statement when we say that these slight cerebral and nerve changes may occur in the progeny of so-called moderate habitual users of alcoholic liquors. If so, here is the "initial lesion," the starting point of the long line of inebriates and insane with which this world is cursed.

"Total abstinence" is the safest remedy for this evil, and until it is universally practiced the production of idiots, imbeciles, insane, and neurotic individuals will not cease. But, it may be asserted that the so-called moderate habitual user of alcoholic liquors will not be answerable for "this train of consequences" if he does not exceed his "physiological quantity." Will any one state what is that safe or "physiological quantity?" We shall certainly lay this waif of hereditary inebriety, insanity, and kindred evils at the door of the so-called moderate habitual user of alcoholic liquors.

But it may be added there are cerebral changes produced by causes other than alcoholic; very well, eliminate from the etiology of cerebral disease one of the most potent of these causes—the habitual use of alcohol in any quantity. Not only inebriety or insanity in ancestry, but all hereditary diseases that tend to weaken the nervous system or give rise to a so-called "*congenital neurasthenia*" are the fertile soil from which inebriety may spring. How many persons born with "a tendency to diseased cravings and paralyzed control," as Dr. Clouston aptly styles it, cannot resist the ordinary shocks of life, readily yield to the seductive influence of some narcotic, alcohol, opium, chloral, cocaine, and become veritable narco-maniacs! What a birth-right!

The question naturally arises, must all born with such a diathesis succumb eventually to inebriety or insanity in some form? We are not prepared fully to answer this question. There are in every community those who are aware of their being possessors of this unfortunate tendency. There are also those who inherit a consumptive diathesis. Instances are on record in which those having a consumptive diathesis have, by selecting their environments, as to climate, occupation and habits of life, successfully warded off the inroads of special disease. May it not be that a person who inherits the inebriate diathesis may also escape the usual results of the same in his own person by observing certain rules, regulations and habits of life? Children born of parents who have not yet become inebriates escape, while children born after parents have become inebriates inherit the inebriate tendency.

Children who inherit the mental or physical traits of either inebriate parent are apt to inherit the inebriate tendency, while other children in the same family escape it.

Moral causes are written down as the chief prevalent causes of insanity proper, second only, in productiveness, to alcoholism. How often, as we have stated, do these congenital neurasthenics, these unfortunates born with a diathesis either inebriate or insane, yield to grief, strong mental emotions, loss of friends or estate, and become either inebriates or insane, when such causes would have produced neither result in a healthy, nervous organization. There are other causes, to which we think the term *accidental* might also be properly applied, and where we generally use the term "acquired inebriety," with which predisposing causes have nothing to do, and where we might with propriety say: "Neither did this man sin nor his parents." Whether inherited or acquired; inebriety is produced by certain exciting causes which may act directly or indirectly upon the nervous system.

Direct causes are those that operate directly upon the cerebro-spinal axis, more especially the cerebrum, viz., sunstroke, head injuries, including concussion and fractures of the skull, cerebral syphilis, and brain tumors.

Moral causes producing more or less mental shock act through the different nerves on the great nerve centres, leaving behind them a profound cerebral disturbance that has as its outward manifestation insanity, or inebriety, or some other form of narco-mania. Other causes act indirectly by *peripheral irritation* through the afferent nerves on the central nervous system. Such are painful ulcers, dysmenorrhœa, urethral stricture, chronic neuralgias, chronic painful diseases of any nature; tania solium has been known to cause inebriety, when relieved of the cause the patient recovered.

Any cachexia that debilitates the nervous system, or that may result in neurotic changes, must be classed among the causes of "acquired inebriety." Chronic malarial poisoning, syphilis, etc., are among these.

Neurasthenia, or nerve exhaustion from under-feeding and over-work, especially if combined with mental anxiety, is a fertile source of inebriety or insanity. *Moral causes* produce this condition usually before plunging the patient into one or the other of these conditions. Certain employments, by their unsanitary surroundings, may produce the tendencies that lead to inebriety. The explanation for the reason that any condition producing unrest, insomnia, pain, mental worry, or mental and physical exhaustion, causing the subject of these conditions to turn to alcohol for relief from exhaustion, insomnia, or pain is found in the fact that *alcohol is a stimulant, an hypnotic, an anæsthetic, a triple capacity*; hence the neurasthenic from any causes flies to it for relief. The

victim of dyspepsia and mal-assimilation, for faintness, and sinking sensations, etc.

The one who cannot sleep finds, especially if the cause of insomnia is mental worry, that *alcohol* is to him a true hypnotic. As an *anesthetic*, alcohol is very pronounced, and in degree will relieve pain as much as opium, chloroform, or ether. The older surgeons recognized this fact, and before the days of modern anesthesia alcohol was used for this purpose. The laity have found out long since this peculiar quality of alcohol, and many victims of pain have sought relief in its anesthetic effects.

The great lesson that all those who attempt to cure the inebriate is that his inebriety has a *cause*, that the inebriety itself is only a symptom of a nascent condition—as someone has said "neuralgia is the cry of a diseased nerve," so inebriety is the cry of a diseased nervous system, produced by causes acting directly or indirectly upon it. "*Tolle Causam*," the motto of every practitioner in dealing with all forms of disease, should also be the motto of every specialist on inebriety. A careful analysis of the cases of inebriety presented to us would show that there are many cases directly traceable to causes or diseased conditions that can be removed, and upon which the inebriety depends. It is the duty of every specialist on inebriety, every physician who would deal successfully with such cases, to trace out and eradicate the cause of the disorder. We cannot remove the cause in all cases; we cannot eradicate hereditary tendencies or certain lesions of tissue resulting from disease or injury; but, in many instances, we can relieve the patient of a painful or exhausting disease and thus cure his inebriety or other form of narco-mania.

MEDICAL CASES IN THE COURTS.

BY HENRY A. RILEY, ESQ.,

OF NEW YORK.

THE DANGERS OF FOREIGN IMMIGRATION.

The steamship companies are making a hard fight to avoid the penalties imposed for violations of the recent law passed by Congress against undesirable immigration. The United States officials have refused to allow a considerable number of pauper and vicious immigrants to land, and the agents of the steamship companies claim that it is a hardship to be obliged to care for them until they can be sent back. The conclusive answer of the Government is that the law is clear on the subject, and the companies should not have brought the unhealthy, insane, vicious and pauper immigrants whom it is desired to shut out. If they are brought, any expense connected with their return must be paid by the steamship companies. The figures of immigration are somewhat start-

ling, and the arrivals from countries where the immigrants are of the most undesirable classes show the largest totals.

The countries of Southern Europe are now outstripping Great Britain and Germany in the number of arrivals. During 1890, 40,883 persons arrived from Russia, 29,994 from Hungary, 62,492 from Italy, and 19,737 from Poland. It would be one of the alleviating circumstances of the disgraceful massacre at New Orleans if it checked in whole or in part the present inundation of Italian immigrants. There is hardly any problem connected with the duties of Health Boards which is so serious and so perplexing as how to deal with the insane and sick foreigners who crowd the steerages of the ocean steamships. It seems difficult to devise a practicable scheme for inspection in foreign ports, and it will perhaps only be a heavy pecuniary loss which will teach the steamship companies to exercise some supervision themselves. It is proposed, among other things, to photograph all rejected immigrants, so as to see that they do not slip in at some later time.

COSMETICS AND SPECTACLES IN COURT.

There have been various attempts in New York to convict of illegally practicing medicine a famous dealer in cosmetics, face washes, etc., whose advertisements, consisting mainly of his own face, are to be found in journals all over the country, but his business seems to go on thrivingly. It is somewhat difficult to distinguish clearly where the line between business and professional dealings lies in such cases, but we think it would be a wise stroke of policy if the aforesaid face washer were to become the *bona fide* holder of a medical diploma by a conscientious course of study at some reputable medical school.

In this connection it may be noted that the optician holds a somewhat doubtful position in regard to the practice of medicine. If he furnishes a customer glasses to cure errors in sight, does he practice medicine so as to run counter to the law requiring the possession of a license? If he investigates the troubles of the eye, determines the errors in refraction and prescribes a combination of lenses such as will remedy the affection, has he crossed the line which makes him an offender in the eye of the law? The French courts have recently held to the narrow, technical theory, and have decided that it is illegal for an optician to give pathological information on the state of the eyesight and to prescribe for any visual trouble a combination of lenses. The optician may be a physiologist, but cannot do anything to remedy the troubles he discovers. It is not unlikely that a broader principle of legal construction would be adopted in this country if the question arises, as it may at any time, concerning the status of opticians.

STEAMBOATS AND CEMETERY VAULTS ARE NOT BUILDINGS.

A New York court holds that where the Civil Damage Law forbids the selling of liquor under certain circumstances in a "building or premises," it does not apply to a steamboat where liquor is sold. The learned judge likened the steamboat to a vault in a cemetery, which he said was not a "building" in the sense meant by the statute against burglary, although it might be above ground.

PIGEON SHOOTING IS NOT CRUEL IN PENNSYLVANIA.

A Pennsylvania statute provides that any person who shall wantonly or cruelly ill-treat, overload, beat or otherwise abuse any animal shall be deemed guilty of a misdemeanor, but the Supreme Court has just held that this does not apply to a member of a gun club who, at a pigeon shooting match, shoots at and wounds a pigeon set loose from a trap, if it is immediately killed when its wounded condition is made known. The Court said:

From the facts found by the jury, the defendant has merely been punished for want of skill. It is doubtless true that much pain and suffering is often caused to different kinds of game by the unskillfulness of sportsmen. A squirrel badly wounded, may yet crawl to its hole and suffer for many hours or days and die. So with birds. They are often badly wounded and yet manage to get away only to suffer. It was not pretended that the Act applied to such cases. The sportsman in the woods is not responsible for the accuracy of his aim under the Act of 1869. At the same time it is manifest that much suffering would be spared wild game if sportsmen were better trained. Skill in shooting upon the wing can only be gained by practice. It is not so with inanimate objects. There accuracy of aim can be acquired by shooting at a mark. It is conceded that the sportsman in the woods may test his skill by shooting at wild birds. Why then may he not do the same with a bird confined in a cage and let out for that purpose? Is the bird in the cage any better or has it any higher rights than the bird in the woods? Both were placed here by the Almighty for the use of man.

In accordance with this reasoning a conviction in the trial court was set aside.

MEDICAL PROGRESS.

Therapeutics and Pharmacology.

THE TREATMENT OF TYPHLITIS.—In the earliest stage, absolute rest in bed, entirely liquid food, and a sedative mixture are necessities. I have generally used the liquor opii sedativus (B. P.), and occasionally joined with it some tincture of belladonna; nupentle has also proved very valuable on two or three occasions. If the pain be very severe, a hypodermic injection of morphine will relieve it for a time, and I have found it disappear "for good" after one injection. A mustard-leaf may be applied to the seat of the pain,

and followed up by a linseed poultice every two hours, or a hot fermentation or spongiopilin if the poultice be too heavy. A few drops of brandy or other spirit sprinkled on the flannel on the side which will touch the skin often takes away pain successfully. It is well in two or three days' time to administer a fair-sized enema of soap and water, and unless the bowels are moved of themselves, this had better be repeated daily. With ordinary care it is quite harmless; it removes whatever may be in the sigmoid flexure, and it stimulates the colon to get rid of its contents, thus probably helping to empty the cæcum and withdrawing the cause of the inflammation. If the vomiting is troublesome, an effervescing mixture with hydrocyanic acid or small doses of lime-water, will be useful. For diet, a little broth, or beef-tea, or arrow-root, or Benger's food, given every two hours in two or three ounce doses will suffice. Milk I regard as not very good food in these cases; unless it be freely diluted with soda-water or lime-water, it is too apt to become a mass of hard curds in the stomach, which may prove very irritating to the inflamed bowel. With the cessation of pain, the lessening of the lump in the groin, and the general improvement in the patient, of course an improved diet and some changes in the medicine become needful. Bismuth, I have generally found to be serviceable in the later stage going on to convalescence. With the surgical varieties into which typhlitis may stray, I will not deal here, as I have no personal experience of them, nor will I touch on that debated question, removal of the appendix. —*Archives of Pediatrics.*

THE EFFECT OF CERTAIN DRUGS ON THE RENAL CIRCULATION.—DR. ALBANESE has published in an Italian journal some important researches on the effects of caffeine, chloral, and curare on the circulation in the kidney, by which he has been led to the conclusion that the amount of urine secreted is not directly proportional to the quantity of blood passing through the organ. When chloral alone was given there was a very marked increase in the volume of the kidney, though, as is well known, this drug has an exceedingly slight diuretic action; while curare, which has a marked diuretic action, was shown to cause no perceptible increase in the volume. When caffeine was introduced into an animal already under the influence of either chloral or curare, it immediately caused a decided increase in the size of the kidney, and at the same time induced marked diuresis. Nevertheless, the increase in size produced under these conditions was not enough to account for the large quantity of urine secreted. Dr. Albanese does not agree with Schroeder that caffeine contracts the renal vessels, but finds that its action is first to increase slightly the volume of the organ and then to

cause a slight dilatation of the vessels. As there appears to be no indication that the diuretic action of drugs is due to increase in circulation or in volume, he is inclined to refer it to some change effected in the renal epithelium.

THE TREATMENT OF IRRITABLE BLADDER.—The best internal medication is iodide of potassium in from ten to thirty grain doses every few hours with large quantities of hot, soft water. This often in the incipient stage will effect a cure in a few days and will give relief in a few minutes. The decoction of the triticum repens which has been so highly praised by some, I have been much disappointed in, as it has appeared to me to do nothing more than act as a diuretic. Tincture of belladonna in some cases is of benefit but cannot be relied upon. Keep the body warm; warm baths with shampooing is of great benefit. Some cases that in the early stages were particularly intractable have been cured by a few weeks' residence at Excelsior Springs, with a liberal use of those iron-manganese waters. Probably they change the nutritive processes that are always at fault, and at the same time wash out the bladder thoroughly by their diuretic action. Relapses are liable to occur, hence great care should be used both as to diet and hygiene, and the first symptoms of relapse promptly treated.—HALLEY, *Kansas City Medical Record*.

POMADE FOR ALOPECIA.—MONIN (*L'Union Médicale*, March 3, 1891), recommends a pomade composed of gallic acid 3 grams, castor oil 20 grams, white vaseline 40 grams, spirits of lavender 15 drops. To be thoroughly rubbed into the scalp night and morning.

CHOREA.—The physician is often at his wits' end to find some efficient remedy for chorea. Tilden claimed to have obtained great benefit by throwing a spray of ether for five or ten minutes along the spine, at the same time keeping up nerve nutrition by appropriate food and exercise. Clark, surgeon-in-chief of the police department in Newark, N. J., reported some time since in the *Times* an exceedingly aggravated case of chorea treated with entire success by antipyrin. Acting upon the hint, we have recently controlled in children from 5 to 10 years of age serious forms of chorea with 5-gr. doses of antipyrin, at first every four hours, and, as the condition improved, three times a day. Very likely there are conditions of the system which would prevent the curative action of the drug, but in these cases it was certainly very effective, acting as a positive curative agent. That this drug is something more than an antipyretic and antispasmodic is seen in its action in renal spasm, the result of calculi, in which it not only controls the spasms but, continued in 5-gr. doses for several days, causes the

uric acid and the sand to disappear from the urine.—*N. Y. Med. Times*.

Medicine.

EHRLICH'S TEST IN TYPHOID FEVER.—C. E. SIMON (*Johns Hopkins Hosp. Bull.*, 1890, 93) refers to the nature of the diazo compounds, and their tendency to enter into combination with aromatic bodies, and cites the first experiments of Ehrlich while endeavoring to discover some of these aromatic bodies in the urine. Owing to the controversy which arose regarding the diazo reaction, especially as to its diagnostic import in typhoid fever, the test has come to be regarded by many as a medical curiosity of no clinical value whatever. The author, however, is convinced by his experience that the original work done by Ehrlich is not appreciated, since his own results fully coincide with those which Ehrlich obtained. After explaining the chemical nature of the reaction as far as it is understood, and the methods which Ehrlich advocated, he details the modification which he has found most convenient as well as most delicate. Two solutions are made, one of 50 cc. of hydrochloric acid in 9.950 cc. of water, and this saturated with sulphanilic acid; the other of a 1/2 per cent. solution of sodium nitrite. To make the test, 40 cc. of the first solution is thoroughly agitated with 1 cc. of the second. A few cc. of this is next thoroughly shaken in a test-tube with an equal quantity of urine. One cc. of ammonia is now allowed to run down the side of the test-tube, forming a colorless zone above the mixture, and at the juncture of the two a more or less deeply colored ring will be seen, the slightest carmine tint—the characteristic of the diazo reaction—being made out by contrast with the colorless layer above and the yellow urine below. Various plays of color may appear in different urines, but in that of typhoid fever there is produced a red coloration, which may vary from an eosin to a deep garnet. Simon has examined the urine of almost every disease which has occurred in the wards of Johns Hopkins Hospital, but has observed the reaction only in cases of typhoid fever and phthisis pulmonalis. He has had no opportunity of searching for it in cases of contagious fevers, in which Ehrlich has occasionally found it present.

The report now made is based upon observations in thirty-six cases of typhoid fever, and the details of the examinations of these are given. The results which he obtained lead him to conclude that, with the methods of examination given by Ehrlich, the reaction may be obtained without difficulty in typhoid fever from the fifth to the thirteenth day of the disease, and that with his own modification it may still be seen as late as the twenty-second day. Its absence from the fifth to the ninth day indicates a very mild case, excepting in children, although this rule is prob-

ably not an absolute one. As it occurs previously to the appearance of the rash, it is a very useful aid in the diagnosis in typhoid fever.—*American Journal Med. Sciences.*

CATARH TREATED BY PEROXIDE OF HYDROGEN AND ARISTOL.—The *Pharmaceutical Era*, March, has a note by the editor to the effect that aristol, dissolved in the lighter petrolatum products, has helped him in a considerable number of difficult cases of naso pharyngeal catarrh. The proportion of the aristol used has not exceeded 10 grs. to the ounce. He begins the treatment by using hydrogen peroxide, in a weak solution, by means of an atomizer. This as a preliminary cleansing measure is beneficial. It is to be followed with the aristol solution as a spray, by which the affected parts are protected as by an antiseptic oily covering. Aristol is harmless in the strength above indicated, and it may safely be prescribed to the patient for home use. The results of this treatment have been the re-establishment of a healthy mucous membrane and a reduction of the catarrhal flow. The cleansing power of the peroxide is admitted on every hand, and favors the more thorough action of drugs than if they are immediately applied.

Surgery.

INDICATIONS FOR TREPHINING THE MASTOID PROCESS.—DR. SCHWARZE (*Deutsche militärärztl. Zeitschrift*, Heft vii, 1890) gives the following indications for opening up the cells of the mastoid process: 1. In recent inflammation of this process with retention of pus in its cells, when the local application of ice and superficial incision have failed to reduce the swelling, pain and fever. 2. In cases of secondary inflammation of the mastoid process, the external meatus should in the first place be emptied of any retained pus. If in adult patients this treatment, together with the application of ice, fail after a week's trial, recourse should be taken to operative treatment. 3. The mastoid process should be trephined in cases of chronic suppuration with repeated swelling, superficial abscess, or fistula, and spreading of the pus to the neck, external meatus, or pharynx, even when there are no apparent symptoms indicative of immediate danger. 4. The mastoid process, even when healthy at its surface, should be opened up in cases of retained pus and cholesteatoma, on the first appearance of symptoms pointing to dangerous complications in the middle ear. 5. The operation should be performed for the prevention of fatal consequences in cases of incurable foul suppuration in the middle ear, although no other symptom may present itself save a persistent ill odor.—*Brit. Med. Journal.*

Bacteriology.

THE ALKALOID OBTAINED FROM THE TUBER-

CLE BACILLUS.—Great interest is naturally attached to the various experiments which have been made in regard to the pathological chemistry of the tubercle bacillus. Although we are now in possession of a pretty full knowledge of the mode of action of the products of the tubercle bacilli as exhibited by the recent experiments made in all parts of the world with tuberculin, we as yet know comparatively little of the chemistry of this substance. An alkaloid was obtained from the products of the anthrax bacilli by Dr. Sidney Martin, and PROFESSOR ZUELZER has succeeded in obtaining a similar body from the bacillus of tuberculosis. A short account of Zuelzer's mode of isolating the alkaloid is given in the *Wiener Medicinische Wochenschrift*, No. 10, 1891. The entire contents of the tubes in which the pure cultures were made were repeatedly treated with hot water acidulated with hydrochloric acid. The solution was filtered, evaporated, and then several times precipitated with platinum chloride; the double salt decomposed by sulphuretted hydrogen, and the liquid again filtered and evaporated to dryness. In this way an almost white crystalline salt was obtained, which was easily soluble in hot water, but with great difficulty in cold. Its solution was light yellow in color. After keeping it for some time the dry salt assumed a light brown color. The chloride when injected into rabbits and guinea pigs exhibited a characteristic toxic action; about one centigram injected subcutaneously produced after from three to five minutes an increase in the frequency of respiration, the movements reaching 180 per minute. This continued for about a quarter of an hour, when the rate gradually became slower. The temperature rose in two out of the ten observations from normal to 102.2° F. Another constant symptom was well-marked protrusion of the eyes, which also appeared bright and shining, with somewhat dilated pupils. The sclerotic was considerably injected. It was remarkable that the protrusion of the eye was more marked on the side on which the injection had been made than on the other. All these appearances disappeared in from fifteen to twenty minutes. Toxic symptoms only showed themselves in three rabbits, and these had received somewhat larger doses, between two and three centigrams having been administered. Death usually occurred somewhere between the second and fourth days. At the site of injections there was considerable redness, and small hemorrhages were found in the muscles immediately beneath. Small effusions of blood were also found in the mucous membrane of the stomach and small intestine. In two cases effusion occurred into the abdominal cavity. The brain was, as a rule, soft and congested. Almost precisely similar results followed the injection of the alkaloid into the conjunctiva.—*The Lancet.*

MEDICAL LITERATURE AND PHILOSOPHY.

If there is one need in American medicine above another, it is literature—words that live. All our physicians are comparatively rich and they occupy a position in the society of the communities in which they live, which is far above that occupied by the same class of men in European countries. We have not only a larger number of readers, but a larger number of men who may become writers. We are astonished, then, that so few examples of the philosopher are produced by our guild.

Certainly there is nothing inherent in medicine which tends to dwarf this manifestation of the human mind. The medical man has an opportunity to gain a deep insight into the soul, and to follow the trend of life in rare and hidden declivities and acclivities. His intelligent sympathy is called into constant and varied activity. He knows the pinch of poverty and the load of luxury. But the inexorable laws of nature are not less familiar to him, and he is trained to follow effect back to adequate cause. To him vice and crime are expressions of conduct which are analogous to the errors or ignorance for the effects of which his services are required. His experience is wide and his touch with man acute. Certainly such a training might well be coveted by a philosopher.

The occupation of the physician gives, then, the pabulum for thought. Does it furnish the motive? Of all pursuits, medicine is the most humane and benevolent. In the true physician's life there is a constant character-building. More

than any other man he knows and feels the moral, mental and physical needs of his people, and he plans for their practical betterment. The betterment of his people is the betterment of all, philanthropy—the motive of philosophy.

But does the busy life of the doctor furnish opportunity for thought? That is as you choose. There are those who, for gain or ambition, fill their lives with petty cares and nothingnesses, who think of naught but the engagements of the moment from the time they are rung out of their beds in the morning, until, after dragging themselves home at midnight, they throw themselves undressed on anything that will serve as a couch, stupid, tired. There are those who fill their working hours with work to gain means to vie, in dress, in equipage and in display, with brokers, merchants and manufacturers. There are those who make their office and their profession an excuse for doing nothing else, and they follow their occupation in a perfunctory manner, as men in their dotage aimlessly sit at the desk where they once transacted business. For these there is no opportunity, as there is motive for thought. But the great majority of physicians, both in country and city, have leisure, and they should dedicate that leisure to philosophy. The amount of leisure may be increased by directing some calls and some cares to younger men.

If our profession furnishes character as well as motive and opportunity for thought, why are there so few thinkers in our ranks? It is because method is neglected. Logic and rhetoric are displaced by novelty or blazonry. It is because there is a sentiment, borrowed from the commercial world, that facts are more than thoughts. Hence our magazines and journals are full of experiments and clinical histories, the former often undertaken without logical limitation, and the latter recorded without rational deductions; both are ungarnished by rhetoric and unseasoned with wit.

In our medical schools no attention is given to the motive and method of medical philosophy. Our colleges are loosely connected with the university, where philosophy itself is taught, and the lyceum, even in this country, forms no part of medical education. However completely the class room instruction is given or the technique of the laboratory acquired, that is a poor equipment which the student carries away, that does not provide for subsequent medical culture.

The multiplicity of medical journals must not be looked upon as an unmitigated curse if their unvaried mediocrity enforces attention to the lack of medical philosophy. In the writer's opinion, there is not a medical author in the United States who has produced anything in the past five years which will last a lifetime. We have careful experimenters, brilliant operators, astute observers, accurate diagnosticians and successful therapeutists, but where are our teachers? The material of our clinics is only partially utilized. Our laboratories, surpassing in equipment those of Europe, are not heard from, and our monographs and compilations are dull, crude tokens of the literary taste and criticism of our profession.

The remedy is not far to seek. The student should be admitted to the study of medicine only after adequate preliminary training. The study of medical literature and philosophy should be made a part of every graduating course, and should occupy a large place in post-graduate education. Special attention should be given authors who write worthy papers, and a few words of encouragement and thanks should be sent by every reader to the author of a paper which has afforded him pleasure and instruction. Those journals only should be patronized that maintain in their columns a respectable standard of literary excellence. In our State and National gatherings those papers should be presented that, other things equal, are clothed in the most becoming garb.

THE DANGERS OF TUBERCULIN.

These have been overstated by some with the same precipitous spirit which others have displayed in their anticipation of its power for good. In the many control observations tuberculin has not been found to injure any non-tubercular person beyond the inconvenience of the febrile reaction. In tubercular subjects, however, the reaction may be alarming in severity and lead to delirium, coma, angina pectoris (Jacobi) collapse and even death. At least one death (Janisch of Innsbruck) has thus been caused by acute tuberculin-poisoning. This danger is more or less in proportion to the intensity of the reaction and it is now universally conceded, that by sufficient caution in beginning with minute quantities and increasing only slowly in dose, such acute dangers can be avoided with certainty. But apart

from the possibility of acute poisoning, other accidents have been observed. The local reaction consists in intense congestion around the tubercular focus, effusion of serum and more or less migration of leucocytes, in short a disturbance verging towards or even identical with severe inflammatory swelling. Under certain conditions such a reaction may prove dangerous, if too intense. The fear that too much reaction in the larynx may necessitate tracheotomy in laryngeal tuberculosis has not been realized, since observers have learned to avoid the rash use of large doses. VIRCHOW has stated that at the autopsy of a child dead of tubercular meningitis he saw the most intense congestion of the meninges in consequence of the tuberculin treatment, that he had ever observed. Yet the few cases of tubercular meningitis in which the treatment was tried did not seem to suffer clinically and although none were saved they did not seem to run a more acute course than ordinarily. In the lungs, however, damage has evidently been done by tuberculin a number of times. VIRCHOW, his assistant HANSEMAN, and various others (Nauwerk) report the frequency of catarrhal pneumonia and of caseous pneumonia with rapid disintegration of lung tissue and even exceptionally phlegmonous infiltration of the lungs in subjects dying while under treatment with tuberculin. In fact, clinically an increased area of dulness and of crepitation can certainly be recognized in some phthisical patients undergoing treatment. Such occurrences evidently mean danger, especially to patients weakened by their previous disease. No doubt some deaths have been hastened by the use of the remedy, and in other instances, like that of GRASSET, life has even been destroyed, where without tuberculin it might have been maintained for a long period. But these unfortunate accidents are getting to be less numerous in the more recent reports, as observers gradually learn to use the substance with more discretion in the selection of the patients, and greater caution in the administration. Various specimens have also been exhibited in Berlin, especially by VIRCHOW, which show that intestinal tubercular ulcers may perforate into the peritoneal cavity, of course with fatal result.

Perhaps the gravest question raised by VIRCHOW and since discussed by many reporters, is the query: Can tuberculin cause a dissemination

of the pre-existing bacilli throughout the body and thus lead to fresh tubercular disease, or even miliary tuberculosis? Numerous clinical observations and autopsies have shown that miliary tuberculosis can occur in patients while undergoing the specific treatment. Of course attention is at present called to every such case, but testimony is yet wanting to prove that miliary tuberculosis is a more frequent complication in patients submitted to treatment with tuberculin than it used to be formerly. Hence it cannot be stated with certainty that a dissemination of the bacilli is produced by tuberculin. But on the other hand the possibility of such an occurrence can also not be denied. It sounds like a warning to hear HANSEMANN declare that within a few months he had dissected three subjects with eruption of miliary tubercles on the epicardial surface, when the records of the Berlin Pathological Institute showed this localization to have been seen only six times in the last ten years.

LIEBMANN claims to have found free tubercle bacilli in the blood of patients during the period of reaction to tuberculin in nine cases. Some of his specimens examined in Berlin by KOSSEL showed that this was due to a deception. The cover-glasses showed that they had been used for the examination of sputum and had been insufficiently cleansed. Various other experts confirmed this opinion. LIEBMANN indeed admitted its possibility, but claimed that in other instances he had also found the bacilli in the blood when no such error could have occurred. EWALD corroborated this so far as he could tell from the slides submitted to him. On the other hand, however, EWALD himself, EHRLICH, GUTTMANN, KOSSEL, PRIOR and others have examined the blood of numerous patients during the reaction with entirely negative results.

It has also been stated by WISSOKI, of Kasan, that the lymph itself contains occasionally tubercle bacilli. In answer to this allegation LIBBERTZ, the manufacturer of tuberculin, has replied that while a few bacilli may occasionally be found in the lymph, they are absolutely harmless because they are dead, since the mode of production guarantees the destruction of all living germs with infallible certainty, and the amount of glycerine in the lymph prevents the growth of any germs which might accidentally get into the flasks from the air.

Can the danger be avoided by any precautions in the administration of tuberculin? The agent in question cannot be compared in its therapeutic effect with any other known remedy, and the rules guiding its administration have to be learned by empirical experience. It is not a substance which, if inefficacious, is at least harmless. An agent exercising such remarkable specific influence on the tubercular process, even in infinitesimal quantities, yet without directly killing the bacilli, is capable of doing harm in unsuitable cases. Its indications and technique require precision like those of any responsible operation.

It has been learned that tuberculin has hitherto been at least useless, if not harmful, in very extensive infiltration of the lungs, in pulmonary cavities (except when combined with surgical measures), and particularly in acute and progressive tuberculosis of the lungs (or any other internal organs) with continuous fever. Great reduction of strength is likewise an unfavorable condition for its action, since the tuberculin reaction, if at all marked, runs down the patient still further. Advanced cases of phthisis have not given sufficiently encouraging results to warrant its use as now employed, in view of the possible dangers.

All observers agree that intense reaction is not of sufficiently greater advantage to the patient than a milder influence of tuberculin to warrant the large doses with which many of the earlier observations were begun. Many authors state that they have found it best to reduce the quantity of the initial dose and the ratio of increase, as their experience became wider. The most extreme advice as to the dosage has just been given by GUTTMANN and EHRLICH, who have charge of the Berlin wards under KOCH's personal supervision. In pulmonary or laryngeal disease they begin with one-tenth milligram increasing daily by one-tenth milligram more until the dose of one milligram is reached. Every second day an injection is now given two-tenths milligrams larger than the preceding one. After two to three milligrams have been tolerated the dose is augmented one-half milligram each time. Later on the quantity is more rapidly increased. Some patients showed thus favorable local reaction without any rise of temperature, except perhaps a few tenths of one degree, and without any discomfort. If any dose sometimes less than 1 mg.)

causes a normal transient febrile reaction, the same dose is repeated every second day until it has lost its pyrogenic influence, whereupon an increased quantity is used. If a continued febrile state is produced, no injection is given until the temperature has become normal, whereupon a smaller quantity, one or even the initial one tenth milligram may be made use of. Any continuous fever the observers regard as a contraindication to tuberculin. The therapeutic results obtained have not yet been published by GUTTMANN and EHRLICH. Until this is done by these authors or others following the same plan, the question whether tuberculin can cure tubercular disease without febrile reaction, cannot be answered definitely. Various accidental observations, especially one case by SENATOR, have taught that some patients who did not respond to the usual doses by general reaction, still were unmistakably benefited. LICHTHEIM has attempted to solve this one case by treating several cases of lupus with the precaution to avoid fever altogether by the use of minimal initial and very cautiously increased doses. He states that while the usual local reaction tending towards a cure of the easily observed patches of lupus was manifested, the patients did neither improve as fast, nor to the same extent as those treated with fewer but larger doses, and that the tolerance to tuberculin and consequent loss of its specific influence occurred before the lupus had healed entirely. He therefore considered a moderate general reaction as an advantage. Other observers have found that after tuberculin had ceased to produce any further local improvement, on account of the tolerance established, an interval of some days or weeks permitted the organism to react again. By adopting this plan RENVERS reports the cure of a case of extensive tuberculosis of the larynx.

THE FINANCES OF THE JOURNAL.

From what was recently suggested by us with reference to the propriety of making an appropriation for payment of the expenses for reporting the proceedings of the Sections, we find that some of our members anticipate that such an appropriation will at once be made, and that the Sections will be thus provided for at the coming session. Much as it may be desirable, such a provision cannot be made at once.

Experience has taught us over and over again that reporting by other than medical experts is *totally unsatisfactory*. Such experts can be obtained, but it will require time to organize such a corps and to adjust them to their Sections. And when the time for such reporting arrives each Section should be provided for and all should share alike.

It will be borne in mind that though the Association may desire to make appropriations, the decision of all such questions is vested in your Board of Trustees. This Board has always been eminently conservative in the handling of your funds, and it has always labored under the embarrassment of not knowing in any given year how much money it could safely appropriate. And this arises from the fact that they could never ascertain until near the close of the financial year how much would be paid in by the members as annual dues, and how much could be earned by THE JOURNAL. For this reason they have been extremely prudent, both with reference to the expenses of the publishing department and for editorial work as well. Under the working of this general policy THE JOURNAL has never owed a debt which it could not pay, and, having money in its treasury, is able to avail itself of the advantages in the market accorded to cash customers. We have learned from critical observation just what our publishing expenses will approximate from year to year, and as there is a steady increase in our annual receipts, we believe the time has come when by recommendation of a special committee to our Trustees, and with their approval, some special appropriations may safely be made which will greatly enhance the value and usefulness of THE JOURNAL. But it is idle to suppose that such appropriations will be made without due consideration or that they can be available for use at the coming session.

THE QUESTION OF REMOVAL.

To those who have so strenuously urged, that the discussion of the question of removing THE JOURNAL to Washington be terminated, and that its pages be devoted to the promotion of medical interests instead, we have simply this to say: By a vote of the Trustees, under whose direction THE JOURNAL is published, the members of the Association were invited to express their views

upon the subject of removal. In answer to that request communications have come to us from every section of the Union. We have felt it our duty to obey instructions, and just in the order in which they have been received these communications have been published. We write to say that with this issue of THE JOURNAL that discussion will be closed. It now remains for the Association to determine for itself, through its Trustees, where THE JOURNAL shall be published, and under what supervision.

THE JOURNAL has occupied no partisan ground in this discussion, though it has had occasion to suggest the modification of some articles which would have been deemed personal by those who strongly favor the removal. Such suggestions have been kindly received, and what might otherwise have led to unpleasant results has thus been averted. In no other way, and never except as stated, has THE JOURNAL sought in any manner to influence the writers who have engaged in this discussion.

EDITORIAL NOTES.

AN AMAZING CHARITABLE EXPENDITURE.—According to the Secretary of the Charity Organization Society of New York, 300 societies and agencies in that city spend \$4,000,000 annually in charitable work.

THE NEW LANGENBECK-HAUS.—The foundation stone of the projected Langenbeck-Haus was laid in Berlin, by Professor Tirsch, on April 4th. This memorial to von Langenbeck is of the most enduring and highly practical kind. As its name might indicate it is not to be a hospital or invalid home, but rather a medical club house—a general meeting place containing lecture-room, library, reading-rooms, refreshment-rooms, etc. It appears that the idea originated with the late Empress Augusta, who gave much interest and attention to medical matters, and whose wisdom in this connection of von Langenbeck's memorial certainly is not to be gainsaid. The last day of the recent German Surgical Congress was set aside for the ceremonies attendant upon the corner stone placing, and the members of that body, together with State dignitaries and representatives of royalty, were present.

A SUGGESTION BEARING UPON TUBERCULOSIS.—Dr. James Braithwaite, of Leeds, mentions

(*Brit. Med. Jour.*, April 11, 1891) the possibility of curing tuberculosis by the destructive powers of other bacilli than those belonging to the tuberculous class. He believes the converse to this is true, viz., that a system thoroughly infected with the tubercle bacilli renders the action of other organisms more or less inert, and in favor of this view he gives the statement of a gravedigger, that those who have died of consumption and been accidentally exhumed two or three years after burial have an undecomposed appearance—are "like wax," while it is not so when death has resulted from other diseases.

"DRUMMING" DOCTORS.—The *Journal of the Arkansas State Medical Society* cries out fiercely—and very justly, indeed—against the unprincipled doctors who prey upon the unfortunate invalids at the Hot Springs. It is hoped the action of the last legislature will avail something in the way of renovation.

TRANSMISSIBILITY OF INFLUENZA.—In opposition to the theory that influenza is a disease not dependent upon personal contact of individuals for its progression, that it is not evolved by the intrinsic operations of a specific poison and propagated through and by means of the ordinary channels of human intercourse, may be mentioned that during the late epidemic observers have found that the course of influenza was independent of, and quite opposed to, the prevailing winds. It travelled slow in Siberia and Russia, but rapidly as soon as it reached the network of railways in Central and Western Europe. Its course was changed by the mountain ranges of Scandinavia, and it invaded Norway, not from Sweden, but from Holland and England. Again, it was deflected by the Carpathians, turning its course in the channels of travel down the valley of the Danube, and ultimately following, in direction and time, the ocean routes to Africa, India, Australia, and this country. In India it has shown the same peculiarities in following the railway lines as has been observed with us.

VENESECTOMY AGAIN.—J. G. Swayne, M. D., has a contribution in the last number of the *Bristol Medical-Chirurgical Journal* entitled "Puerperal Eclampsia," and in which he seeks to show the great value of timely venesection. After reviewing a case, he says: "This case is only one of many others which I have published from time to

time, in order to prove the efficacy of venesection in puerperal convulsions, and thus to rescue, if possible, from unmerited oblivion a most valuable but, in the present day, most unaccountably neglected remedy." Further on, in a note appended to his paper, the author, having late cognizance of Dr. Pye-Smith's defense of venesection before the Royal Medical and Surgical Society of London—noticed editorially in this Journal not long since—continues as follows: "It is, therefore, very gratifying to find that I am not alone in my attempts to rescue so important a remedy from oblivion."

DISEASES OF THE TROPICS.—An authoritative consideration of those diseases which give to the tropics their greatest stigma brings out the conclusion—based largely upon military returns—that although malaria is the most widely diffused and the most commonly talked of and dreaded affection, yet dysentery is without question the most fatal.

FAULTY CONSTRUCTION OF HOSPITALS.—In an Editorial Note in the last number of *THE JOURNAL*, in making reference to the recent fire in the Brooklyn Naval Hospital, while censuring such construction of Hospitals as will permit by means of wooden elevator shafts and dust shutters the rapid communication of fire to the entire building, we were led to infer that the Naval Department had been remiss in its duty in replying to solicitations from its medical officers.

The following note from one well known to the profession, and so related as to be an authority upon this subject, so entirely exonerates the Naval Department from such criticism that we cheerfully give place to it:

To the Editor:—I regret that *THE JOURNAL* has been misled in its account of a fire at this Hospital by a malicious sensational report in a daily paper. The reflections on the Washington authorities are unauthorized, uncalled for, unfounded and untrue. I have never made any request that has not been generously granted and without stint. The trifling damage was promptly repaired at slight expense.

ALBERT L. GIBON,

Medical Director in charge.

Brooklyn, N. Y., April 26, 1891.

MEDICAL ITEMS.

THE MEDICAL SOCIETY OF THE STATE OF NORTH CAROLINA will hold its annual meeting at Asheville, May 26, 27 and 28, 1891. The effort will be made to make the meeting one of un-

usual interest and pleasure. The scientific and the social features offer special attractions. The railroads and hotels are granting special rates. North Carolina ought to be more fully represented in our National Organization, and we trust that her leading medical men will give their influence in this direction.

ILLINOIS STATE MEDICAL SOCIETY, John P. Mathews, Carlinville, President; D. W. Graham, Chicago, Secretary. This old and able Society will convene this year at Springfield on May 19. Its sessions are always interesting, and the programme before us gives assurance that the coming meeting will well maintain the standard of excellence so long established.

DR. F. S. BILLINGS, who formerly held that position, is again appointed Director of the Pathological Laboratory of the State University of Nebraska.

JAPANESE CENTENARIANS.—The authorized report of the census returns of Japan, completed December 1, 1889, shows a total population of upwards of 40,700,000. Sixty-five persons were found who had reached their one hundredth year of life, 45 were one hundred and one, 13 were one hundred and two, 4 were one hundred and three, 1 was one hundred and four, 9 were one hundred and five, 3 were one hundred and six, 1 was one hundred and seven, and 1 had reached his one hundred and ninth year.

THE LUXURY (?) OF TUBERCULOSIS.—Now that cod-liver oil has advanced about 400 per cent. in price, and with tuberculin at no inconsiderable figure, there may be some measure of satisfaction to the proud consumptive in the reflection that he is certainly not having "cheap" dosage.

AN UNFORTUNATE OCCURRENCE.—A late exchange comments under the heading: "Arsenic in the Massachusetts Legislature." This certainly awakens our deep sympathy that so poisonous a drug should get into an assembly of lawmakers. We have often heard of whisky getting into such distinguished bodies—it has even been hinted that our National Legislature occasionally suffers in this way—but this is quite the first time we have ever heard of an arsenious legislature. We would recommend the hydrated peroxide of iron at once.

TOPICS OF THE WEEK.

GOOD POINTS FOR STUDENTS AND DOCTORS

Dr. W. H. Steele, in *Items of Interest*, says:

Our colleges will turn out an unusually large number of graduates in the spring, who undoubtedly expect to locate in some Canaan of promise and build up a practice. It shows push and pluck for a young man to strike out for himself, much more so than to buy out a practice or partnership. We all, who have tried it, know it requires many things besides a sheep-skin to successfully conduct a practice. I will give a few points, many of which I have learned from sad experience, so that others may profit by my errors and losses.

Don't neglect your business.

Don't misrepresent anything to get business.

Don't try to economize by using cheap material or poor instruments.

Don't make any promises, either financial or professional, that you cannot fulfill.

Don't lock your office during office hours to go off on a frolic, or to attend to any side show, or for any other purpose that can be avoided.

Don't try to tear down a competitor's reputation on which to build your own; it makes a rotten foundation.

Don't forget that the poor have feeling, as well as the rich, and are just as deserving of respect and your best services.

Don't be cross to the little ones; some day they will be men and women, and they will remember you for good or for bad.

Don't fail to take several good journals, and to keep yourself posted on all new instruments and improvements.

Don't buy a bill of goods because they are cheap or you can get time on them. Do a cash business, and be a cash customer to every one. It will wonderfully enhance your reputation in the community.

Don't repeat some slanderous story that may have been told you by talkative patients while operating for them.

Don't let a "good enough job" go out of your office; do your very best every time for your patient. By this means you will improve your work, improve your patronage, and improve your bank account.

Don't fail to be prompt in collecting and paying your bills, if from any cause you feel obliged to give or receive credit. By so doing you will gain and keep the confidence of all.

Don't use tobacco in any form; it is certainly of no benefit to you, and, to say the least, will work you harm physically, morally and financially.

Don't use intoxicating liquors, for intemperance is the rock on which many a good practice has been stranded, and any indulgence leads to excess.

Don't forget there will come a time when your eyes will grow dim, and your hand lose its cunning. It is when you are young, healthy and prosperous that you should lay aside something to fall back on in sickness and old age, and when you will be glad to be able to reflect that you are leaving a busy, bustling world better

for the part you have played in it. A serene, satisfied old age, well provided for, must be delightful.—*Cincinnati Medical News*.

CLINICAL ART

Visitors to the Paris Salon are only too familiar with a certain phase of Impressionist art which depicts medical men carrying on their everyday work, and even follows the hand of the surgeon into a variety of practical details ranging from vaccination to ovariectomy. Our own English school does not lend itself so readily to this unpleasant realism, but every now and then we find a peep taken into the hospital ward or the sick room, and some little idyl of domestic medicine worked out with a quiet pathos which is apt to call into sudden activity the functions of the lachrymal gland. Many of us remember John Faed's "From Dawn to Sunset," and "Tired Out," and Fildes's stalwart navy gazing with speechless misery at his dead child can hardly be forgotten by those who have seen the impressive work which now finds a somewhat inappropriate resting-place at the Holloway College. This year the brilliant painter of bright scenes returns to his early love, and gives us another touching little domestic drama on the stage of humble real life. A sick child lies on a hastily improvised bed in the middle of a poorly-furnished room, and the doctor, before he disturbs its half-comatose sleep for further examination, takes a long and keen diagnostic glance at the pale face and limp lying arms. There are obviously difficulties in the case, and he is evidently puzzled, whilst the uncertainty of the situation is reflected by the father, who, standing in the background beside his despairing wife, eyes the arbiter of his child's destiny with an anxious look, and waits patiently for the verdict. The lamp-light throws a ruddy glow over principal actor in the scene, and through the eastward window we see the chill light of the early morning just beginning to make itself felt. When visiting the studio our representative met several physicians who were speculating with keen professional interest as to the intentions of the artist. What is the matter with patient? Is the prognosis hopeful or hopeless? and on these points a wholesome difference of opinion existed. One pronounced for infectious meningitis, and a necessary fatal result. Another, relying on the absence of certain diagnostic symptoms, decided in favor of fever, and a favorable prognosis. Mr. Fildes, on being appealed to, wisely declined to give any opinion of his own. The picture is simply called: "The Doctor," and he leaves those who look at it to puzzle out its meaning for themselves, and if one object of art is to stimulate thought and encourage mental speculation, then success has been perfectly attained, and the pathetic force of this masterly work will combine with the rich and harmonious coloring and the perfection of complete yet unobtrusive detail to render it one of the most attractive pictures of the coming Academy. It will be good news for the art-loving world to hear that it has been bought by Mr. Tate, and that we may therefore hope to find it included in the fine collection which he has so generously presented to the nation. By a curious coincidence Mr. Locksee has this year worked on very much

the same lines as Mr. Fildes. Under the name of "The Crisis," he represents a sick girl sleeping that slumber which may end in the more permanent sleep of death, or lead on to the joyful awakening into convalescence. Worn out by long watching the anxious father fixes his eyes on his daughter's face, and waits for Nature to say the word which will fill him with joy or sorrow. There is something very fine about the blended look of half-puzzled expectation mixed with a kind of hopeful resignation, which fills the eyes and shades the brow of the impressive father's head, which rests on and is partly hidden by the thin hand. And again we begin to try and look into future. But it is very difficult to say how things are to go in this case. The patient is thin and worn and thoroughly exhausted, but sleep may do much for her, and "the crisis" may be past when she wakes. As the visitor turns away from the canvas he cannot help recalling a well-worn quotation from Hood:

We thought her dying when she slept
And sleeping when she died.

—*Brit. Med. Journal.*

OLD AGE AS A FACTOR IN SURGERY.

Dr. N. F. Graham, of Washington (*Medical News*, February 7, 1891), reports eight cases observed by himself, and refers to others published in this country, which show wonderful recuperative powers in very old men and women. With regard to advanced age being a contra-indication to surgical operation, it is held that if the patient be in fair general health, with an hereditary tendency to long life, mere old age is not a good reason for withholding treatment, either with the view of prolonging life, or for the relief of acute suffering. As a rule, old people, Dr. Graham states, tolerate pain better than the young, but with them shock is more severe and not so quickly rallied from. In shock lies the greatest danger to the aged, and if the patient rallies, the prognosis, so far as repair is concerned, may be considered good. They endure operations for pathological conditions, such as new growths, remarkably well. Their recovery from accidental wounds is not so rapid.

LADY APOTHECARIES.

The tyrant, man, is slowly but surely being driven behind the last breastworks of his professional monopolies, and woman is everywhere more or less triumphantly asserting her "rights." Not content with prescribing drugs she now insists on compounding them. A *projet de loi* has just passed the French Chamber of Deputies admitting properly qualified women to the practice of pharmacy. Frenchmen are nothing if not chivalrous, and it is therefore somewhat surprising to find them considerably behind other nations in this respect. In Norway women have for the last six years been allowed to study pharmacy and to manage and own drug shops. About ten women are at present employed in pharmaceutical establishments either as pupils or assistants, but not one of them has presented herself for the final examination. In Denmark only two women have, in the course of many years, taken up pharmacy, and neither of them has "qualified." In Finland there are seven female

apothecaries, none of whom, however, have passed the final examination; indeed, since 1884 no lady has applied for admission. In Russia ladies have, since the beginning of last year, been entitled to become pharmacists, and nine, having completed the requisite preparatory studies at Zürich, have passed the Russian examination. Courses of instruction in pharmacy for women have already, as we stated a week or two ago, been established in one of the St. Petersburg hospitals, from the dispensary of which the fair pillmakers have already succeeded in ousting the rival sex. The facts which we have mentioned seem to show that the strong-minded sisterhood have not the devouring enthusiasm for pharmacy which they display for medicine, though it is an occupation for which they are in some respects especially well fitted. This indifference may perhaps be due, at least in some measure, to the comparatively little opposition they have met with in the attack on that particular male citadel.—*British Medical Journal.*

TUBERCULIN.

The following charade was written by a patient recently under treatment by Koch's method at Banff, Scotland, and sent to the *Lancet* by Dr. William Fergusson:

My first lies at the root of things,
With homely earth is soiled,
Yet at the festive board of kings
Is always welcome—boiled.

My second o'er the level green
Impels the polished ball;
Where "cannons" rattle it is seen,
Yet loves the peaceful "stall."

My third around the green earth lies,
No angel ever saw it;
'Twas never viewed by mortal eyes,
Yet men must somewhere draw it.

When wasting sickness crowns the ill
By hapless men endured,
My whole fresh strength and hope instils,
And whispers "Be thou cured!"

—*Boston Medical and Surgical Journal.*

THE MONKEY SOLVES THE PROBLEM.

Monkeys have a keen sense of imitation and are always prone to copy their master's movements whenever fancy strikes them. Seldom, however, is it that a monkey has proved itself useful by such an undesirable propensity. Yet one of these inquisitive creatures has, we understand, recently performed a feat in the matter of medicine-taking, and by so doing has earned for itself a reputation which deserves recognition. This is how it was: A practitioner recently received a box of Count Mattei's medicines, and one of his children getting hold of the box gave it to a tame monkey in the house. The animal very soon broke open the box, and taking a vial of anti-canceroso, which is used as a cure for leprosy, swallowed 750 globules, besides some other fever medicines. The proper method of taking the anti-canceroso is to dissolve one of the globules in a quart of water, and the dose is a teaspoonful at a time. The monkey, however, is not only quite well, but as lively as ever, and must now be unperturbed to leprosy. Clearly, if the monkey had been able to read he would have been more discreet with Count Mattei's remedies, but as no harm happened to him, the presumption is that the remedies are harmless however they are taken.—*Medical Press.*

PRACTICAL NOTES

FOR ITCHING IN SCARLET FEVER.

Itching in scarlet fevers is not always agreeable, and it has never been supposed to be a favorable sign, but St. Philippe (*Rev. Mens. des Mal de l'Enf.*, February, 1890), according to A. F. C., in *Archiv. Ped.*, in a paper presents the following conclusions, viz.:

1. Scarlatina is often a disease which is accompanied by itching.

2. This variety usually has a favorable prognosis.

3. The itching is due to the fact that the eruption is not intense and the cutaneous lesion not very profound.

The best application for the relief of this itching, or almost any other for that matter, is the following:

R. Campho-phenique, $\overline{\text{ss}}$.

Abolene unguent, $\overline{\text{ss}}$.

℞. Sig. Apply night and morning.

Another advantage is that it is in the direction of personal disinfection.—*Medical Mirror*.

DENTAL CARIES.

The following prescription has been suggested:

R. Acid. tannic., gr. lxxv.

Tinct. iodinii.

Tinct. myrrhæ, $\overline{\text{aa}}$ f $\overline{\text{ss}}$.

Potassii iodidi, gr. xv.

Aque rose, f $\overline{\text{ss}}$ vj. ℞.

Add a teaspoonful to a small glass of water and use daily as a mouth wash.—*Pharm. Record*, March 5, 1891.

CHRYSAROBIN IN PSORIASIS.

Dr. Unna recommends

R. Chrysarobin, 5 parts.

Salicylic acid, 2 parts.

Ichthyol, 5 parts.

Vaseline, 88 parts.

Made into an ointment and to be rubbed into the affected parts.—*Nouveaux Remèdes*.

FOR ANGINA PECTORIS.

The indications for treatment during the paroxysms are the following (Dr. W. R. Jackson, *Va. Med. Monthly*, Feb., 1891):

1. To relieve pain, by hypodermic injections of morphia or inhalation of ether or chloroform.

2. To stimulate the heart to action—by use of brandy, whisky or sulphuric ether by hypodermic injections or by the mouth.

3. To keep or maintain the continued rhythmic action of the heart, and to diminish the arterial tension, which is best done by nitroglycerine, nitrite of amyl, or electricity or galvan-

ism. The cases most amenable to treatment are the purely cardiac kind, without any cardiac lesions.

Dr. Austin gave arsenic as a tonic and preventive. It is well to put your patient on a tonic of iron and arsenic, or quinia with sugar-aromatic. If there is a gouty or rheumatic diathesis, it should be met by appropriate treatment, and a suspicion of syphilis should likewise be suggestive. Sea-baths and travel are to be recommended. The patient should avoid all commotion—moral and physical; he should lead a quiet, cheerful life, and should religiously abstain from tea, alcohol, and tobacco.—*College and Clinical Record*.

APPLICATION FOR ACNE ROSACEA.

Dr. Unna, of Hamburg, has produced what he believes to be an ideal preparation of ichthyol for application in cases of acne rosacea. It is prepared by combining it with starch in the following manner: Forty parts of starch are moistened with twenty parts of water, and this is well rubbed up with forty parts of ichthyol, and finally, one or one and a half parts of a strong solution of albumen intermixed with it. This is applied to the skin at night; it dries in about two minutes, and can be easily washed off in the morning. As there is no fatty matter in this varnish it is eminently suited as an application in lupus erythematosus, or, as Unna calls it, "ulerythema centrifugum," in which fatty matter is to be avoided.

FOR ERYSIPELAS.

R. Ichthyol, $\overline{\text{ss}}$ ij.

Ether, $\overline{\text{ss}}$ ij.

Collodion, $\overline{\text{ss}}$ iv. ℞.

S. Paint over and around infected area.

—*Proc. Med. Journ.*

ACETANILID AS AN ANTISEPTIC.

Early in the days when acetanilid was first introduced, some prominence was given to its antiseptic properties, but in the crowd of substances specially introduced as members of the "antiseptics," this field of usefulness for it was forgotten. Quite recently its virtues in this direction have been accentuated by the descriptions of its use instead of iodoform in the treatment of hard and soft venereal sores. The chancre is simply dusted with the powdered compound, and the result is said to be a rapid and complete healing. The advantages of the odorless and non-toxic acetanilid over iodoform need no emphasis; while for hospitals and dispensaries its cheapness would further recommend it if increased observation confirm these statements.—*Provincial Med. Jour.*

SOCIETY PROCEEDINGS.

Tennessee State Medical Society.

*Fifty-Eighth Annual Meeting held in Nashville,
April 14, 15, and 16, 1891.*

FIRST DAY—MORNING SESSION.

The Society met in Watkins Hall, and was called to order by THE PRESIDENT, DR. GEO. A. BAXTER, of Chattanooga, at 10:30 A.M.

Prayer was offered by REV. C. D. ELLIOT, of Nashville.

The first paper read was by DR. T. J. HAPPEL, of Trenton, on

ABSCESSSES.

He said this field was a profitable one for thought and investigation, especially in the direction of diagnosis. So far as the treatment goes, the Latin expression *ubi pus, ibi incisio*, gives us the therapy of such cases in a few words, so far as their last stages are concerned. The prophylactic treatment is a different matter. Everything that can be done to prevent pus, to prevent the development of an abscess, must be resorted to, but when pus is present the knife is the instrument for relief. An aspirator can remove the pus itself, but the cause of it, the pyogenic something, is left behind. A free outlet must be given to the pus, the cavity carefully cleaned, perfect drainage secured, arrangements made for thoroughly flushing the diseased organ with antiseptic fluids, the strength of the patient maintained by a generous diet, and nature aided by an abundance of pure fresh air to repair the broken-down constitution.

Dr. Happel reported a case of abscess of the spleen. He said this was a rare trouble, many of our best authorities never having met with a single case. He had in the course of seventeen years practice found two cases; one due to pressure upon the organ; and the other to chronic malarial poisoning. He also reported a case of abscess of the cornea forming hypopyon, and one of the liver, which came under his observation. In closing he called attention to the peroxide of hydrogen as one of the best, if not the best, of all agents, used to cleanse and restore to a normal state all pyogenic membranes, surfaces and cavities. As one writer expressed it: "It hunts out pus in all its ramifications as a ferret does a rat."

AFTERNOON SESSION.

DR. GEORGE R. WEST, of Chattanooga, read a paper on

OVULATION AND MENSTRUATION.

He said that individual opinions and theories are as those who love darkness rather than light, and insist upon remaining in darkness rather than to be disturbed by the entrance of facts which

might bring light. The subject of ovulation and menstruation, their dependence or independence, is one of these benighted fields where individual opinions and theories run riot, and where the light of facts gained from research and experience is so perverted as to render uncertain the supposed certainty that has previously existed.

After giving a résumé of the literature on the subject, Dr. West drew the following conclusions:

1. That the increased familiarity with the pelvic organs, the result of modern surgery, has not materially added to our knowledge of their functions.

2. That though the ovular theory of menstruation has not been overthrown, yet the weight of accumulating evidence seems against it.

3. That the most recent observations point to a common nervous origin for both ovulation and menstruation, and yet an individual independence.

DR. THOMAS M. WOODSON, of Gallatin, contributed a paper entitled

TREATMENT OF PNEUMONIA; THE PAST AND PRESENT METHODS; HAS THE RATE OF MORTALITY BEEN CHANGED?

He briefly reviewed the literature on pneumonia to illustrate the opinions of medical teachers and writers. He was glad that Hare, of Philadelphia, in his work on "Practical Therapeutics," revived the old lines of treatment. He extolled *veratrum veride*, and said that in the first stage of the disease it is very useful as a medicant. Its two alkaloids possess different influences and that between them they fulfill every object that is sought for. *Jervine*, a powerful vaso-motor depressant, relaxes the walls of the blood-vessels everywhere, at the same time it quiets the action of the heart by an action over its muscle or ganglia as to reduce its force, thus preventing engorgement of the lung; while *veratroidine*, by stimulating the inhibitory nerves of the heart, also slows its beat, fills the ventricles and allays excitement. The advantages of *veratrum veride* are its completeness and rapidity of action; the fact that it preserves in healthy blood-vessels the blood which may be needed in the crisis, if the disease is not aborted, and its safety, is a point largely in its favor. In the second stage to prevent heart failure by engorgement from over-distension, Dr. Hare gives digitalis with strychnine to stimulate the respiratory centres; that he thinks alcohol in the second stage is inferior to digitalis; carbonate and muriate of ammonia are valuable adjuncts in the second and third stages. He uses opium sparingly for troublesome cough in the later stages, and not in the first stage.

In the first stage of croupous pneumonia the indications, said the speaker, are clear: 1. To control the circulation and diminish the determination of blood to the lungs; 2. To reduce

the temperature if high; 3. Allay pain by both physical and physiological rest; 4. Support the vital powers.

The first two indications are met by veratrum viride better and with more certainty than any other. The third, to allay pain, we have but one remedy—opium or its salts, which stands without a rival. Fourth, to support the patient with especial reference to failing heart and respiratory centres; digitalis, strychnine and alcohol for the later stages.

More than twenty years ago the speaker expressed the opinion that in inflammatory affections veratrum viride was a sedative of the greatest value, controlling the action of the heart as effectually as blood-letting, without the exhaustion incident to the latter. Arterial excitement is reduced by it, while the vital forces are economized. It is especially adapted in pneumonia in the stage of engorgement in which it appears to bring about prompt resolution. It may be used in the treatment of children with safety. Its constitutional effects having been secured, there is a reduced force and frequency of the circulation, reduction of temperature and respiration, and an amelioration of all the symptoms of the disease. While extolling the virtue of veratrum viride, he would not rely on it alone in pneumonia, as opium was unquestionably entitled to a prominent place, palliative and curative in its action, allaying pain, cough and nervous irritation, available in the latter as well as the early stages.

PHTHISIS PULMONALIS, WITH ESPECIAL REFERENCE TO PROPHYLAXIS,

was the title of a paper contributed by Dr. J. R. Buist, of Nashville.

As physicians, impressed with the claims of suffering humanity, we should never relax our efforts as long as consumption, with its multiplied ills, afflicts our race, with its sickness, pain, and death. Nor have we any right, as scientists, to despair of the ultimate triumphs of knowledge and the practical results of scientific research. The acknowledged failure of all the proposed plans for the cure of phthisis, based upon therapeutical agents, should lead us upon other lines of effort for its destruction. The impossibility of procuring for the mass of consumptives the benefits of climate and altitude, even if these benefits approximated the value some assign them, should admonish us to look to the higher plane of preventive medicine in dealing with this disease.

Regarding Koch's *paratubercle* as a remedy for consumption, Dr. Buist said the high expectations so recently excited in these inoculations do not seem to be verified. Certainly for advanced stages of phthisis, and many other conditions of tuberculosis it is unsuited and positively dangerous; and it is not settled whether any benefit can

attend its use in the incipient cases. In making this statement, he would not detract anything from the real value and merit of the discovery, and meant no disparagement of the genius of Koch.

Preventive medicine is after all the acknowledged aim and end of scientific research. Though still in its infancy, it has accomplished wonders for humanity. And it is obvious that its first and highest triumphs are to be won among the class of zymotic and infectious maladies. The power of prevention is incalculably more precious than any therapeutical measures. It is therefore highly incumbent upon us individually and collectively to assure ourselves of the modern theory of consumption, and so convinced, we should direct our attention and efforts to a rational prophylaxis of this fatal disease.

It may be said that the true difficulty is to get the public to realize its danger from various sources, and still more to have wise prophylactic measures adopted. This is in the main true; yet education can perform wonders. The benefits of sanitary reform are now acknowledged and trusted, although fifteen years ago it met with indifference and opposition.

The speaker closed with the words of Dr. E. O. Shakespeare, of Philadelphia: "What use was it for Koch to have made his discovery of the infectious nature of the bacillus tuberculosis, if the practitioners of medicine, those who come in direct contact with the people, who are the natural agents for arousing such a public sentiment and enforcement of laws for the protection of public health, utterly neglect to act upon the ample and exact knowledge which we possess concerning the etiology and prophylaxis of tuberculosis."

EVENING SESSION.

The public were invited to attend this session. Addresses were delivered by Hon. William Litterer, Mayor of Nashville, Hon. H. H. Norman, and Judge J. M. Dickinson. Dr. Geo. A. Baxter also delivered at this session the Presidential Address, his subject being *Topics of Import to the Profession and Public*. The address was scholarly, very instructive, and was listened to with marked attention.

SECOND DAY—MORNING SESSION.

Dr. J. S. Cain, of Nashville, read a paper on

CHRONIC ENDOMETRITIS,

in which he said the question as to the localization of the chronic form of endometritis is rendered more prominent than that of the acute form on account of the conflicting opinions, entertained by distinguished authors and teachers. None, he believed, questioned the very frequent occurrence of chronic cervical endometritis, but Drs. Emmet, Bennett, and other very distinguished authorities, almost absolutely ignored the existence of chronic

corporeal endometritis as a special disease, and consequently except for the relief of hemorrhages, and to meet temporary emergencies, discountenance all intra-uterine medication, relying entirely upon treatment directed to the urethra and vault of the vagina. But the great preponderance of medical authority is averse to the opinions entertained by these gentlemen, and with the latter class he was entirely in accord.

Chronic endometritis and the conditions necessarily allied therewith are the most common as well as the most important diseases with which the gynecologist has to deal. This condition is often a sequel to the acute form of the disease, and grows out of repeated acute attacks. It matters not how or from what source the acute outbreaks originate, whether from catarrhal, specific, traumatic or internal constitutional causes, they are often, but not always, the starting-point from which not only the endometrium but the entire uterine and periuterine parenchymatous structures become involved. He would here venture the assertion, that while the change in structure and function of the lining membrane of the uterus often seem to be the most prominent conditions, and those which demand our first and most careful attention, this tissue is probably never chronically diseased without a corresponding involvement of the entire uterine structures.

Treatment.—While the curette, as has been said, is a blind instrument and capable of doing harm in careless and incompetent hands, yet for the removal of fungoid vegetations and adenoid degenerations from the endometrium, it affords the surest, speediest and safest means as yet devised. Dr. Cain is accustomed to following the curetting by an application of Churchill's tincture of iodine or diluted carbolic acid, as is the usual practice, and always precedes the treatment by a careful washing out of the vagina and uterus with a disinfectant of one to two thousand corrosive sublimate.

In cases where this treatment is not admissible, or where it has failed to afford relief, his next reliance is on the electro-chemical action of negative galvanism, in removing the vegetations after the method of Apostoli. This is accomplished by introducing an electrode, insulated to near the point, into the uterine cavity, and connecting with the negative pole of the battery, connecting the other pole with a large pad of moistened potter's clay, sponge or prepared cotton, placed over the abdomen. The time for employment of the galvanism at each treatment should be from ten to fifteen minutes, and the treatment should be repeated about twice a week.

The strength of the current to be employed will depend much upon the acuteness of the particular case, and the susceptibility of the patient to electrical treatment. The chronic cases always require the stronger current. The dosage

may be fixed at from ten to three hundred milliamperes; the minimum is, in his judgment, too small to accomplish any good results, and yet physicians with much larger experience have had to employ it.

This line of treatment he considers free from many of the objections to others; it is cleanly, free from pain, and exempt from danger. Unlike cauteries and escharotics it can be limited in its influence and produces no deleterious effects upon the sound tissues, nor does it leave a raw and exposed surface like the curette to absorb poisons and septic agencies, and while it removes the vegetations it imparts renewed tone and vitality to the diseased organ.

(To be concluded.)

DOMESTIC CORRESPONDENCE.

LETTER FROM NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

The Treatment of Phthisis by Inoculation with Vaccine Lymph—Bellevue Hospital Training School for Male Nurses—Hospital Saturday and Sunday Association—The Establishment of Public Hospitals—Care of the Insane Poor—Miscellaneous Items.

It will perhaps be remembered that some time ago reference was made in this correspondence to the treatment of phthisis by inoculation with vaccine lymph, as practiced by Dr. J. Hilgard Tyndale. At the last meeting of the New York County Medical Association, Dr. Tyndale, in reading a paper on this subject, presented nine patients who had all shown the presence of the tubercle bacillus in their sputa, and most of whom had cavities in their lungs, who, he claimed, had all either recovered or were in a fair way to recovery from their tuberculous trouble. Altogether he has treated twenty-three carefully selected cases by this method, and he stated on this occasion that in the other fourteen the same favorable results had been noted as in the nine that he exhibited. He lays great stress on exact and localized diagnosis, and would select for inoculation cases in which are found more or less active cavities and infiltrations, with suppurative expectoration, coupled to a not entirely hopeless general condition. No cases of pure connective tissue proliferation, nor of general or localized cirrhosis of the lung (in other words, peri-bronchitis), and no cases of purely mechanical disturbances of respiration caused by the binding down of lung tissue by pleuritic adhesions, nor cases in which diffused dry, sibilant râles, heard all over the chest, distinctly point to obstruction in the upper air passages, are regarded as suitable for this method of treatment. Cases in which

the bacilli are no longer localized, but have become disseminated throughout the lungs, are admitted by Dr. Tyndale to be incurable by his own or any other treatment that has as yet been devised.

For each injection he usually employs the contents of one capillary tube, about 2 drops, of pure vaccine lymph, and he mixes with it 15 drops of distilled water and 1 drop of glycerine. The fluid is injected subcutaneously near the seat of trouble by means of an ordinary hypodermic syringe. At first the injections are made at intervals of from six to eight days, but after the bacilli have disappeared and the expectoration has become sparse and of a mucus character, they are made only once in every two, three or four weeks. At the third and fourth injections the contents of two tubes are often used. No violent reaction follows the injection, but the temperature usually rises from one to two degrees in the course of from eight to twenty hours, and more or less frontal headache is apt to be experienced. As long as the signs of active tuberculosis remain, no supporting treatment is adopted, but as soon as these have disappeared, means for the promotion of blood and fat formation, varied according to the circumstances of the special case, are at once inaugurated. Lung gymnastics, consisting of five deep inspirations every twenty minutes throughout the day, also constitute an important part of Dr. Tyndale's treatment.

So far as known, the twenty three cases mentioned are all that have as yet been treated by the vaccine lymph inoculations, but the impression made by the paper and by the nine patients exhibited was such that it is probable that before long the method will be tested by a series of investigations sufficiently extended to show whether it is really of permanent value or not. In regard to the treatment of tuberculosis in general, Dr. Tyndale's idea is that more than one animal and chemical virus will be found to accomplish the same object, and that the secret of the whole matter lies to a great extent in a correct diagnosis and the adaptation of the remedy to each individual case.

Since the meeting at which his paper was read it has been suggested that a commission should be appointed by the County Association to make a thorough investigation and report upon Dr. Tyndale's method, and it is probable that this will be done.

A very interesting occasion was that of the graduation of the first class of pupils from the Bellevue Hospital Training School for Male Nurses, which was established two years ago through the liberality of Mr. D. O. Mills, and was probably the first institution of its kind in the world. There were seventeen graduates, and a remarkable feature in regard to the class was the diversity of the localities from which its members

hailed. One was from New York City, two from other parts of the State of New York, two from New Jersey, two from Pennsylvania, one from Connecticut, one from Massachusetts, one from Michigan, and one each from London, Berlin, Copenhagen, Edinburgh, Paisley, Scotland, Wales and Clare, Ireland. The diplomas were presented by the founder, Mr. Mills, himself, and addresses were delivered by ex-Mayor Abram S. Hewitt and the Hon. Chauncey M. Depew. Since the school was established there have been in all 115 pupils, and there are at present 43 in attendance.

The Hospital Saturday and Sunday Association's distributing committee recently met at the Mayor's office, and made the annual apportionment of the money resulting from the annual public collection for the hospitals. The amount collected this year was \$58,297, and of this \$40,000 was distributed to the various institutions represented in the Association in accordance with the number of free days of treatment furnished by each during the year 1890. The hospitals receiving the largest amounts are the following: Mount Sinai Hospital, \$6,789; St. Luke's Hospital, \$5,930; Montefiore Home for Chronic Invalids, \$3,020; German Hospital, \$2,890; and the Hospital for Ruptured and Crippled, \$4,677. On Easter Sunday the Rapid Transit Electric Railroad Company, of Newark, N. J., generously gave all its receipts to the three hospitals of that city which are supported by charity—St. Michael's, St. Barnabas and the German. The traffic was unusually heavy, and as many of the passengers paid bills instead of nickels for their fares, the amount realized was the handsome sum of \$902.

The noted Fayerweather will contest having been brought at last to an end, many of our hospitals will receive substantial additions to their endowments. Thus the Woman's Hospital is to get from the estate \$210,000, St. Luke's Hospital, the Presbyterian Hospital and the Manhattan Eye and Ear Hospital each \$50,000, and Mount Sinai Hospital, the New York Eye and Ear Infirmary, the Manhattan Hospital and Dispensary, the New York Cancer Hospital and the Montefiore Home for Chronic Invalids, each \$25,000.

A gratifying mark of progress in this close of the nineteenth century is the establishment of public hospitals in so many of the smaller cities and towns of the country. In the village of Sing Sing, on the Hudson, there has just been opened the Ossining Hospital, a substantial building containing thirty rooms and fitted up with all needful appliances. It stands on a two-acre lot in a healthful location, and is lighted with gas and supplied with water from the village system.

The bill appropriating \$454,000 for carrying out the provisions of the law establishing State care of the insane poor, which was enacted a year ago, has happily passed the Legislature and re-

ceived the Governor's signature. The State policy in regard to this matter having been once settled, good faith required that the appropriation should be made, to give full effect to the beneficent measure which was the result of so many years of agitation and effort. Yet it had to encounter the same opposition that this grand reform movement has always met with, and at one time Albany fairly swarmed with county supervisors and with lobbyists who spared no effort to defeat it. While the bill was pending the Medical Society of the State of New York was in session, and it adopted resolutions strongly urging its passage. The annual report of the State Commission in Lunacy for 1890 shows that the money thus appropriated will be sufficient to provide for all of the insane poor now unprovided for by the State, when used in conjunction with appropriations which have been already made and with other provisions which have been secured. The claim which had been put forth by the enemies of this movement, that the State hospitals for the insane are all badly overcrowded, is shown by the report to be almost entirely without foundation. Moreover, the Commission shows in its estimate that it has left a liberal margin for the annual increase in the number of the insane in the State. While the report clearly indicates that the Commissioners do not favor overcrowding in the State hospitals, it is undoubtedly their opinion that even if this should exist to some little extent, it would be much better for the patients than to be crowded together in the wretched quarters and with the inadequate care provided by the county poor-houses.

Until within a comparatively recent period insanity was believed to be increasing with great rapidity relatively to the increase of population. The report of the State Commission in Lunacy shows, however, that at present insanity is apparently decreasing, rather than increasing, relatively to the general population. Notwithstanding the incalculable harm that has resulted from the legal division of the insane into two classes, the acute and chronic, or so called incurable (one of the great evils against which the long agitation in this State has been directed), there is reason to believe that this favorable result has been chiefly brought about by the improved methods that have been more or less generally adopted in the treatment of the insane. Consequently, there can be little question that when all the insane poor of the various countries shall have been brought under the beneficent influences which prevail at the State Hospitals under their present enlightened management, the results will be even more satisfactory. The statistics presented in the report of the Commission show that in the State Hospital at Utica the percentage of recoveries among the patients has been 19.53, in the Buffalo hospital 29.19, in the Middletown hos-

pital 16.16, in the Poughkeepsie hospital 18, and in the Asylum for Insane Criminals 3.96. The report outlines the history of the State's system of caring for its insane dependents, and shows that the present plan of management is in accord with the policy that has been adopted for the prisons and other large interests that require appropriations by the Legislature.

Like liberty, however, reform in the care of the insane by the State must depend on eternal vigilance for its maintenance, requiring constant efforts on the part of its friends. The State Commission in Lunacy, which has been so prominent in the movement, has naturally made enemies not only of a host of county officers, but of all the corrupt elements of the managing boards of the State Asylums, which have been practically superseded by it. The unchecked expenditure of from two to three million dollars yearly has been taken from them, and, as has been pointed out, the expenditure of large sums of money derived from State and other non-local sources by local boards can hardly be otherwise than extravagant and corrupt. The prize of the two or three millions annually required for the State hospitals for the insane is a tempting one, and there is considerable danger that a ring of public plunderers, now drawn from the hospital boards, or held in check by the Commission in Lunacy, may succeed in abolishing that body, and re-establishing their rights to these institutions as a local franchise and to the function of investigating themselves and their agents.

Since the appropriations required for the present needs of the State hospitals were made by the Legislature, a bill has been passed by the Senate which materially modifies the law for the State care of the insane so far as it applies to the State hospital at Middletown, which is in charge of a staff of homœopathic physicians; and the State Commission in Lunacy, the State Charities Aid Association, and all those who worked to secure the enactment of the existing law, are naturally strongly opposed to the adoption of this measure. Under the present laws, all the State hospitals are authorized to receive paying patients from all parts of the State, provided that there is room for such patients not required by the pauper and indigent insane for whose benefit these institutions are established. The proposed legislation (adopted by the Senate, but not yet by the Assembly), seeks to free the Middletown Asylum from this condition, leaving it optional with this hospital to fill its wards entirely with paying patients should it so desire, without restriction of any kind. The second part of the bill is designed to allow the Middletown State Hospital to receive indigent and pauper patients without restriction from all parts of the State, and to fix the charge to the counties for their maintenance.

This legislation, as pointed out by Prof. Chas. F. Chandler, President of the State Charities Aid Association, with which the State Care Act originated, would nullify two important features of the latter act. "That an effort," he says, in a letter addressed to the Chairman of the Committee on Public Health, "should be made to break up the State Care system, as provided by this law—a law which for three years has been under discussion by the entire press of the State, by three successive Legislatures, and has received the verdict of popular approval—before the law has had time to go into full operation, is much to be deplored. On October 1st, 1890, the State was divided into State asylum districts.

This provision of the law causes no injustice, and is working satisfactorily, and therefore I wish to express my dissent from that portion of the bill which gives the Middletown hospital the right to receive pauper and indigent insane patients from any part of the State, as tending to break down the State districting of the State Care act. Should the same privilege be extended to all the State asylums the valuable State districting features of the State Care Act would cease to exist. The other important feature of the State Care Act which will be nullified, should the Legislature grant special privileges to the Middletown State Hospital, is that which provides that after the State has been divided into asylum districts, the charge to the counties for their pauper and indigent insane in State asylums shall be the same for all the counties of the State. It seems to me right and just that the charges to the counties for the care of their pauper and indigent patients in State asylums should be the same for all the counties of the State, and therefore I am obliged again to express my dissent to that portion of the bill which exempts the Middletown asylum from this provision of the act. As President of the State Charities Aid Association I respectfully protest against the enactment of this special legislation, which I believe to be opposed to the best interests of the pauper and indigent insane of this State."

The University Medical School, which has just celebrated its 50th anniversary, had a very large graduating class this year, 203. The Bellevue graduates numbered 152, and those of the Long Island College Hospital, Brooklyn, 82. At a meeting of friends of the University called for the purpose of aiding in raising a fund of \$500,000 for the needs of this institution Prof. Alfred L. Loomis recently stated that the medical department of the University on its present basis had reached its utmost possible limit of success. This year there was a matriculating class of 694, so that all the professors received salaries sufficient to compensate them. Without an endowment, however, it would not do to raise the standard of the school, since maintenance was dependent on

the tuition fees of the students, and to do this would cause a falling off of about 30 per cent. in the attendance. Dr. Loomis said furthermore on this occasion that rich New Yorkers were pouring out their money for hospitals, while they allowed educational interests to suffer. He believed that at least \$500,000 had been spent for hospitals in this city which ought to have been devoted to the latter. Consequently, New York had more hospitals to-day than the needs of the sick and indigent required, and nearly one-third of the patients in these hospitals who are able to be taken care of elsewhere.

P. B. P.

To the Editor:—In your issue of October 11 there appears a paper by Dr. Wm. H. Daly, a nose and throat specialist of this city, on "The Medical Treatment of Diphtheria," containing statements that call for correction. The paper was read at the forty-first annual meeting of the American Medical Association at Nashville, June, 1890, and strange to relate, its claims for originality were not contradicted. The special treatment for diphtheria to which Dr. Daly refers, and which he claims as his own, is that by large doses of calomel. He says: "You will pardon me if I undertake to draw your attention again to a well-tried plan of treatment which I had the honor of bringing to the notice of the profession in a paper entitled, 'The Simplest and most Efficient Treatment of Diphtheria,' which I read before the Congress of the American Laryngological Association in Philadelphia in 1886." I propose to prove to you that the writer of both of these papers shows a lack of justice toward his professional brethren that is truly marvelous. The treatment of diphtheria by large doses of mercury was first practiced by Bretonneau in 1821, and his method of administering the drug, and his history of cases appear in the Transactions of the Sydenham Society. Dr. Daly may be ignorant of the work of Bretonneau, but he cannot enter such a plea as regards the work of the late Dr. Wm. C. Reiter, of this city. Dr. Daly and Dr. Reiter were fellow-townsmen and contemporaries, and Dr. Daly, like the rest of Dr. Reiter's friends, cannot forget the earnest enthusiasm with which the calomel treatment was urged. Dr. Reiter's sole aim during his later years was to impress the value of the calomel treatment on the profession, and in pursuance of this effort he published in 1878, through the Lippincotts, of Philadelphia, a monograph entitled, "The Treatment of Diphtheria Based upon a New Etiology and Pathology." It is to this little book that Dr. Daly is indebted, not only for his ideas, but in many instances for his very words. Finally, Dr. J. Chris. Lange read a paper on the calomel treatment before the Mott Club, of Pittsburgh, of which Dr. Daly was a member, in 1882, and published it,

together with the discussion which it provoked, in the *Philadelphia Medical Times* of January 8, 1883.

It may seem a gratuitous labor on my part to make this correction, but I am convinced of the need of it by the citation in Keating's *Cyclopædia of the Diseases of Children*, of Dr. Daly as the sponsor for the calomel treatment. A proper regard for the memory of Dr. Reiter prompts me to speak.

ADOLPH KENIG, M.D.

33 Ninth St., Pittsburgh.

SPECIAL CORRESPONDENCE.

Shall The Journal be Removed to Washington?

ACTION OF THE AURORA (ILL.), MEDICAL SOCIETY.

At the regular meeting of this Society, held April 7, the following preamble and resolution was read, and unanimously adopted:

WHEREAS, we as members of the Medical Profession, feel a deep interest in the prosperity and welfare of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, situated as it is near the geographical centre of its numerous subscribers and contributors, with facilities for its early and rapid distribution unsurpassed in the United States, and believing that its removal to the City of Washington, in place of being an advantage, would certainly be a detriment to its usefulness. Therefore, be it.

Resolved, that we cast our unanimous vote to have it remain in its present location and under its present able management.

To the Editor:—I have been a member of the American Medical Association for a number of years, and have taken THE JOURNAL ever since its first publication, and live 900 miles from Chicago, and always receive it on the day of its issue, and find it increasing in value and interest; therefore, cannot see what advantage could be derived from changing the place of its publication from Chicago to Washington. Under such circumstances I say, let it remain in Chicago.

A. M. MILLER, M.D.

Bird-in-Hand, Pa., April 20, 1891.

To the Editor:—The publication of THE JOURNAL is preeminently a business enterprise. If the place of publication is to be changed, good and sufficient reason must be shown for such change; no argument being necessary to maintain a location when it has prospered. No argument has been brought forward which a business man would consider for a moment as a reason for changing his place of business. Therefore, do not change.

HORACE M. STARKEY, M.D.

Chicago, Ill., April 23, 1891.

To the Editor:—Those doctors at Washington who have endeavored to transfer THE JOURNAL, had better come to Chicago; they will find much to their own advantage. At least the good of THE JOURNAL and Association can be best served at the geographical centre, Chicago. Decidedly no! Do not remove THE JOURNAL to Washington. "Do not put it under a bushel."

J. CH. DODDS, M.D.

Denver, Col.

MISCELLANY.

MISSOURI STATE MEDICAL ASSOCIATION.—The annual meeting of this Association will be held at Excelsior Springs, May 19th, 20th, and 21st.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from April 18, 1891, to April 22, 1891.

Major Alfred A. Woodhull, Surgeon, is detailed to represent the Medical Dept. of the Army at the International Congress of Hygiene and Demography, at its meeting in London, Eng., from August 10 to 17, 1891. He will leave his present station not later than June 1, 1891, and will proceed to London. After the adjournment of the Congress he will return to his proper station. While abroad under this order, and before returning to the United States, he will visit on official business such points in Great Britain as may be deemed necessary by the surgeon General of the Army. By direction of the Acting Secretary of War. Par. 17, S. O. 91, A. G. O., Washington, April 22, 1891.

Capt. William F. Knudler, Asst. Surgeon, is relieved from duty at Jackson Mts., La., and will report in person to the commanding officer, Ft. Logan, Col., for duty at that post, reporting also by letter to the commanding General, Dept. of the Missouri. By direction of the Acting Secretary of War. Par. 2, S. O. 88, A. G. O., Hdqrs. of the Army, Washington, April 18, 1891.

Official List of Changes in the Medical Corps of the U. S. Navy, for the Week Ending April 25, 1891.

Medical Inspector D. McMurtrie, detached from Navy Yard, New York, and to the U. S. S. "Lancaster."
Medical Inspector Edward Kershner, detached from Marine Rendezvous and to Navy Yard, New York.
Surgeon C. G. Herndon, from Naval Hospital, New York, and to the Marine Rendezvous.
P. A. Surgeon James E. Gardner, ordered to Naval Hospital, New York.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine-Hospital Service, for the Two Weeks Ending April 15, 1891.

Surgeon P. A. Bailhache, to represent the Service at the annual meeting of the California State Medical Society. April 8, 1891. Detailed as chairman of Board for the physical examination of officers, Revenue Marine Service. April 14, 1891.

Surgeon John Vansant, detailed as chairman of Board for physical examination of officers, Revenue Marine Service. April 14, 1891.
Surgeon H. W. Austin, detailed as chairman of Boards for physical examination of officers and candidates, Revenue Marine Service. April 14 and 15, 1891.

Surgeon J. M. Gassaway, leave of absence extended five days. April 15, 1891.

Surgeon G. W. Stoner, to proceed to Alpena, Mich., on special duty. April 12, 1891.

P. A. Surgeon W. P. McIntosh, detailed as recorder of Board for physical examination of officers, Revenue Marine Service. April 14, 1891.

P. A. Surgeon G. M. Magruder, detailed as recorder of Board for physical examination of officers, Revenue Marine Service. April 15, 1891.

Asst. Surgeon T. B. Perry, ordered to examination for promotion. April 6, 1891.

Asst. Surgeon R. M. Woodward, ordered to examination for promotion. April 6, 1891.

Asst. Surgeon H. T. Goodwin, ordered to examination for promotion. April 6, 1891.

Asst. Surgeon G. T. Vaughan, ordered to examination for promotion. April 6, 1891.

Asst. Surgeon B. D. Geddings, detailed as recorder of Board for physical examination of officers and candidates, Revenue Marine Service. April 14, 1891.

Asst. Surgeon J. C. Perry, detailed as recorder of Board for physical examination of officers, Revenue Marine Service. April 14, 1891.

Asst. Surgeon J. F. Groenevelt, to join station (New York). April 13, 1891.

Asst. Surgeon M. J. Rosenan, to proceed to Cairo, Ill., for temporary duty. April 13, 1891.

CHICAGO, MAY 9, 1891.

No. 19.

ADDRESSES.

THE PRESIDENT'S ADDRESS.

Delivered at the Forty-second Annual Meeting of the American Medical Association, at Washington, D.C., May 5, 1891.

BY WM. T. BRIGGS, M.D.

OF NASHVILLE, TENN.
PRESIDENT OF THE ASSOCIATION.

Ladies and Gentlemen: My heart swells with pride when I look over this vast assembly of the representatives of a profession, distinguished alike for its antiquity, its scientific attainments, and its usefulness; a profession which forms the true link between science and philanthropy.

You, gentlemen, as members of this Association, have been delegated by your local Associations, from every part of this Grand Republic, from the Kennebec to the Rio Grande, from orange groves and golden sands, from mountains clad in eternal snows, and valleys smiling in perpetual verdure, to represent them on this occasion.

You are here with no selfish motives, nor purposes of self-aggrandizement, nor to excite or perpetuate sectional antipathies.

Indeed, as physicians you should recognize no section; with you there should be no East, no West, no North, no South. You are here solely for the promotion of science and for the good of the human race. You are here to maintain the honor and dignity of the profession and to hold aloft the flag of honorable medicine. You are here to lay your contributions,—the accumulations of your study and observation,—upon a common altar for the common good; to worship at the sacred shrine of medicine and to renew your fealty to the noble profession to which you have devoted your lives and linked your fortunes. You are here to exchange experiences with each other, to separate by discussion the grains of truth from the wordy chaff in which they may be hidden, to renew friendships and to weave more closely the bonds of professional brotherhood.

As physicians you have an almost superhuman mission to fill. Life, the greatest of human blessings, and health, the greatest stimulant to earthly enjoyment, are the issues with which you are called to deal.

The chief objects of your professional work are

to preserve the one, and to procure the other. The goal of your ambition and desire is almost at the end of human capacity. It is your province as well as your earnest desire to know all the secrets of organization. You would have the formative crystal and germinal spot made transparent. You would enter the microscopic world and witness the wonders therein revealed. Indeed, you would, if it were possible, search into and unravel the very mysteries of the vital principle.

To this perfect knowledge you aspire.

It is doubtful if man's intellect, great as it is, can ever compass all that he so earnestly desires, yet by constant and faithful work he may approach nearer and nearer to its consummation.

He has before him rich and boundless fields for research, from which the eager and enthusiastic explorer may gather the richest prizes. To these fields the future generation of physicians will be attracted in the hope and belief that as man advances in knowledge and approaches nearer to the understanding of the perfect wisdom, which designed his physical organization and by which he is brought in relation with the world around him, he will be enabled to solve more and more of the difficult problems which have, for ages, baffled and perplexed him, and to elevate the profession of medicine to a position more nearly akin to that accorded to the exact sciences.

We live in an age of progress, and all the arts and sciences are advancing with gigantic strides. With the aid of steam and electricity time and space have been almost obliterated. The most distant parts of the world have been made neighbors. A fact developed or an important discovery made, is flashed in the shortest conceivable time to the most remote parts of the globe and given to the public without money and without price.

The science of medicine has kept pace with, if it has not outstripped all other sciences.

It has been completely revolutionized within our day. The microscope, chemical analysis, clinical observation and vivisection are carrying the medical mind with wonderful velocity in pursuit of knowledge, far beyond, indeed, the most sanguine conceptions of even a third of a century ago.

In every part of the habitable world blessed

with the light of civilization, active, busy members of our profession endowed with high culture and incited by the noblest resolves are enthusiastically engaged in unravelling the mysteries of disease and seeking the means and methods of treatment for the mitigation and relief of suffering and the prolongation of life.

That the full benefit of the labors of American physicians might be attained and utilized, it was essential that the members of the profession scattered over an area of country of almost inconceivable extent, should be brought into associated action,—should be organized into a body by whose annual discussion an exciting, vivifying and healthful influence might be exerted over the length and breadth of the land, until a correct and noble sentiment had been engendered in the bosom of every member of the profession.

Through the brilliant genius and indomitable energy of one who is known as the "Father of the Association," this grand body was formed and has ever been sustained and fostered by his parental solicitude, in which he has been nobly assisted by the cordial coöperation of his brethren. More than a generation has passed since its organization, and many of the master spirits which were present and assisted in the inauguration of the enterprise have joined the silent majority, leaving it as a precious heritage to their successors, who should be actuated by the same spirit which inspired those who had preceded them, and with the same energy and zeal endeavor to manage the high trust with an eye single to the honor and glory of the profession.

A few of those who assisted in its organization in 1847, weighed down with honors and years, still make annual pilgrimages to this Medical Mecca and by their presence and counsel add increased interest to its meetings.

Chiefest among these is Nathan Smith Davis, to whom, more than any other, is due the credit of establishing and perpetuating this National Association—venerable, distinguished, renowned, may he be long spared to counsel and assist in the deliberations of the body!

The purposes of those who organized the Association were to protect and promote the interests of the American Medical profession, to maintain its honor and respectability, to advance its knowledge and to extend its usefulness.

That these desirable objects have been accomplished to a very great extent is a matter of history.

Through its moral influence it has united the great mass of physicians from Maine to Texas, and from the Atlantic to the Pacific in the bonds of fellowship, many of whom at great sacrifice of personal comfort and pecuniary interest, come to the annual meetings with hearty fraternal greetings for each other, and who, becoming touched

as with a living coal of fire, renew their vows of faithfulness and loyalty to the cause in which they are engaged, and form the high and noble resolve to devote their time, talent and lives with still greater assiduity to their chosen profession.

If the Association had done nothing more than to have accomplished this unification of the Medical profession, it would have performed a service entitling it to an imperishable name. It has, however, been an active and powerful agent in the promotion of medical science and in the dissemination of useful knowledge. It has excited a spirit of improvement among the masses of the profession which nothing can stay.

Another great benefit conferred by the Association was the establishment of an *esprit de corps* in the profession, by the preparation and adoption of a Code of Ethics which comprises the great principles of truth, honor and justice, in regulating the relations of physicians to each other, to their patients and to the public. It should be and is the written law clearly defined and of acknowledged force and effect that prevails from one end of the country to the other. It forms an impassable barrier between the sheep and the goats, the clean and the unclean, the physician and the charlatan.

The strict observance of the Code has done more than anything else to maintain harmony in the profession and to elevate it in the public estimation. It embodies the true spirit of the Golden Rule,—“Do unto others as you would have others do unto you.”

Every one who enters the profession should be provided with a copy of the Code and should make it the guide of his medical life. It will serve as a talisman to the young physician, and will be the best safe-guard against the snares and pitfalls which environ his pathway in his early professional life.

It would seem that every honorable and high minded member of the profession would be willing to endorse and be controlled in his intercourse with his medical brethren and the public by every article of the Code.

It is, however, to be regretted that there are some, who undoubtedly possess high order of talents, and are justly distinguished, who have an utter repugnance to the observance of certain parts of the Code and hold themselves aloof from the Association in consequence.

They, *probably* are as proud of our noble profession as we, and are equally as anxious for the advancement of its interests, but can they conscientiously affirm that the motives by which they are influenced are pure and unselfish? And should they, a small minority, put their opinion against the unbiased and unselfish judgment of the wisest and most experienced in the profession? And when, too, nine-tenths of that profession endorse

and are guided in their actions by the spirit and letter of the Code?

The chief object—indeed the fundamental idea of those who originated the Association was the improvement of the American system of medical education and the elevation of the standard of requirements for the professional degree. Never was there a greater expenditure of effort, illuminated with genius and learning, to accomplish these two great objects. Never was there more eloquent and philosophical reports to any organization than those presented by the committees appointed year after year, to this body; yet it seemed, after all efforts in that direction, as far from fruition as at its initial meeting. The resolutions proposed and adopted from time to time, were sufficiently pointed and admirably adapted to the end in view, but, unfortunately the Association had no legislative authority or power to enforce its enactments, and its moral suasion and influence was not great enough to move the college to accept their counsel.

In 1850 the medical colleges were invoked to meet and correct the great evils of the prevalent plan of teaching in this country, but they did not respond to the appeal. Since then, on various occasions, delegates from the medical colleges have met and discussed plans for the advancement of medical education but have failed, from want of coöperation and united action, to make the desired changes.

The idea of making such changes in the medical education of our youths in a country so diversified and of such extent, in a few years, was probably Utopian. Such radical and lasting changes can only be effected by the slow work of time. There has, however, been a gradual elevation in the standard of education, fully equal to the progress of the country in every other department of human learning.

To those of us who entered upon our medical studies twenty, thirty, or forty years ago it will be gratifying to visit any well organized medical college and witness the many improvements and the increased facilities for the instruction of its pupils. The extended curriculum of instruction, both in the didactic and clinical departments, the patient and painstaking work in the laboratories of Chemistry, Physiology, Pathology and experimental Therapeutics; the special instruction in the department of Surgery, Obstetrics and Gynecology and Ophthalmology; the resources afforded by hospitals and dispensaries, and the admirable arrangement for the prosecution of Practical Anatomy in the dissecting room, all attest the wonderful progress and advancement made in medical teaching since our pupilage.

I am ready to maintain that the advantages and facilities for medical instruction in our country even at the present time are quite equal to those

of any other, and that our medical colleges have produced as able, learned and successful practitioners as ever graduated from other institutions, and while I am willing to admit that our transatlantic brothers have excelled us in experimental work, we excel in all practical departments of medicine. Chassaignac, the eminent Parisian surgeon, exclaimed a few years since that America held the scepter of the Surgical world; and more recently Virchow, President of the late International Medical Congress, said, "The American Medical world to-day excels in Surgery, Midwifery and Dentistry."

What American physician is not overwhelmed with thankfulness when he remembers the pain and anguish which has been prevented through the great boon of anæsthesia, which in the providence of God was given to our country; who will ever tire of hearing of the great blessing conferred on suffering women by the genius and skill of McBowell, or of the marvellous changes made in Gynecological Surgery by the prolific brain and cunning hand of Sims.

Had America done nothing else than contribute these gifts to the world it would have been made famous for all time to come.

The great advance made in our medical education has been undoubtedly due to the frequent and very able discussions which have been held on the subject in this Association, and to the eloquent and philosophical reports of committees of education which have been so often appointed, and apparently with so little effect,—but the seed so wisely sown in the organization of this body have germinated and are now of hardy growth, and it is hoped in the near future will attain maturity and yield a harvest of abundant and perfect fruit.

The professional public have been aroused on the subject of a higher and better education than has been furnished by the old system, even, as improved by modern advancement. This professional sentiment has extended to medical teachers, and I believe that a majority of American medical colleges are now ready to acquiesce in the demands of the profession for a higher education, and that they will execute to the fullest extent the wishes of the Medical College Association as expressed at the meeting in Nashville last year. And when the medical colleges shall have entered upon the higher education which they have determined to do, the American Medical Association will have cause to congratulate itself in the accomplishment of the chief object of its organization.

The success of the Association in these and other purposes has been very great, even beyond the expectations of its most sanguine friends. "As a social and professional reunion of kindred spirits and great minds, its memories afford perennial

delight. It has given impetus to the progress of polity and science, it exercises moral suasion rather than authority, it has brought together a bright constellation of intellect, cemented the bonds of friendship among good men and true, and has formed a luminous track of light in the firmament of the Æsculapian heavens throughout the length and breadth of the land." It has passed safely through the perils of infancy, avoided the errors of youth, has entered upon the full estate of manhood, and now occupies an advanced position in the deliberative assemblies of the world. Constituted of delegates coming from every part of the country and representing every interest of the profession, it is really a great National Congress; it is the only legislative body of the profession which can regulate the action of its members and harmonize their conflicting interests; and it is full time that it should assume the power of legislating for the whole American profession and demand that its enactments be observed. That this power may be attained and exerted beneficially, greater efforts should be made to bring into the Association every prominent and influential member of the medical profession, especially those who have thought proper to alienate themselves from its deliberations. Let us ask them in the true spirit of conciliation to throw aside their narrow prejudices and renew their allegiance to the Association. Let us relegate all the asperities of the past to oblivion and remove the unpleasant feelings which have existed for the past four or five years, to the end that the medical profession of America may be, "Though distinct like the billows, yet one like the sea;" that it may be truthfully exclaimed, "Behold how good and how pleasant for brethren to dwell together in unity." Then, encouraged by the knowledge of the moral power of the Association, let us not be satisfied with what has been done in the past but press on in the good work we have undertaken, toward perfection, securing as much beauty and finish for the body as is compatible with the imperfections of the human understanding.

Now that the College Association has adopted all the requirements for improved medical education, which the Association has been so long urging, and for which, in fact, it was established, it is eminently proper, and I would urgently press its importance on the members, to pass a resolution, that after the changes contemplated have gone into effect, no medical man who has received a degree from a college which has not adopted the improved method of teaching, and no professor nor attaché of such college shall be eligible as delegates or members of this Association.

This great moral support is due those colleges which so heartily took up the burden that the Association has carried for nearly half a century,

and I hope it will be cheerfully accorded them.

It is a well known fact that a very large proportion of the members of this body at each session, come from the vicinity of the place of meeting, many of whom have never been present at the sessions before, and are ignorant of the parliamentary usages of the body, or entirely indifferent what business is before it, or how it is disposed of. So that a few only of its members shape and conduct the entire business. Indeed, the transaction of routine business of the Association is uninteresting and irksome. Sometimes in the discussion unpleasant feelings are engendered and animosities formed which interfere materially with the harmony necessary for the welfare and usefulness of the Association. I would therefore respectfully suggest, that all business matters of the Association, should be referred without discussion or comment, to an executive committee composed of two members to be appointed by every State Society in affiliation with this body, who, after mature deliberation, shall report them back to be adopted or rejected, as the Association may determine; and that the morning session, which has been heretofore consumed in the transaction of ordinary business, shall be occupied in the discussion of living, burning questions selected by the business or the nominating committee, and that members especially qualified to discuss the questions chosen, shall be selected a year in advance, that they may be thoroughly prepared for the duties assigned them. Such discussion will be greatly conducive to the advancement of medical science and will attract a great number of the best medical men who are not interested in the routine business of the Association, and who are consequently never present at the meetings.

To still further promote science and add to the interest of this body, I would suggest that prize essays provided for in the organization, and for so long a time ignored, shall again receive the attention they deserve. I feel sure that it is the sincere desire of every member of the Association that it progressively improves in the quality of the work it presents to the profession from year to year. There is, in my opinion, no exercise which will add more to the interest of the Association, or do more to promote science, than the presentation of essays which will be offered in competition for suitable prizes.

In this connection it may be well to call the attention of the Association to the fact, that original research and experimental investigation have not received the attention from American physicians, which their importance demands. Living as we do, in a comparatively new country, our energies have been directed to the promotion

of the practical, and more directly, useful departments of the profession than to the minute investigation of scientific subjects; and our government, while the most liberal and best under the sun, has never seemed to comprehend that the cause of science, especially medical science, would be greatly advanced, and its own honor proportionately increased, by the establishment of schools for original investigation and experimental research. It has not kept pace with the other enlightened governments in scientific enterprises. It is hardly to be expected, however, that in the rapidly changing political dynasties, the attention of our legislators could in the near future be directed to the advancement of pure science. This must, for the present, at least, be left to the progressive spirit which animates our universities, and to private laboratories which are being established in different sections of the country. Would it not be advisable for the Association to establish a Section of Experimental Research, to which young and enthusiastic devotees might be encouraged to make and repeat experiments in all the departments of medicine? It would certainly form a very interesting and useful Section, and would tend to advance science and add greatly to the interest of the Association.

It was a happy conception of one of our most distinguished presidents to make the establishment of an Association Journal the burden of his inaugural address, and so powerfully did he impress its importance upon the minds of the members of the Association, that a committee was at once appointed to take into consideration his suggestion, with the result that a weekly Journal was established to take the place of the annual volume of Transactions. That the change has been a valuable one none will deny. It has asserted and maintained the honor, dignity and power of the medical profession as a factor in civil life; it has tended to enlighten and strengthen the profession, and to lead it in the proper direction. Its design has been to represent in the broadest sense the true status and progress made in this country and to give expression to the thoughts, purposes, and will of American physicians. It has in the short period of its existence given evidence of its power in the advancement of its purposes. Yet it must be acknowledged, notwithstanding the great learning and untiring energy of its editors, together with the faithful coöperation of its trustees, that it has never attained the ideal excellence which should characterize the organ of this great body of physicians. It may require years to bring it to the desired standard, and it should be determined here to-day, that every effort shall be made to advance it to the highest standard. To effect so desirable an object it is necessary to make provision for an ample annual income.

Nothing less than from seventy-five to one hundred thousand dollars should be considered ample. To many, this sum may seem chimerical, but it is not. If every member of this body would constitute himself a live, active agent to solicit subscriptions from his brother physicians living in his vicinity, and to assure himself that THE JOURNAL is on the table of every doctor within his reach; and if to this is added the income which may be derived from legitimate and properly selected advertisements, the necessary fund will be assured.

Next in importance to finance, is the selection of an editor, able, learned, highly educated, with ample editorial tact and business qualifications, who will devote all of his time and talent to his editorial duties. He should be empowered to spend money liberally in obtaining scientific material, original communications, translations and reviews from every part of the world. He should have absolute control in the selection of matter for THE JOURNAL; he should manage THE JOURNAL boldly, vigorously and with an eye single to the honor and glory of the profession.

To such an editor a salary should be given which would make him independent in a pecuniary point of view. Not less, I would suggest, than ten or fifteen thousand dollars should be paid to him annually. Then, with elegant paper, perfect typography and attractive binding, THE JOURNAL will add lustre to the Association and honor to the profession.

The necessary fund, which can be easily raised by proper exertion, will not only sustain THE JOURNAL in the best style, but will afford a sum in addition which can be used in many ways to the advantage of the Association.

The future location of THE JOURNAL is a matter of such importance as to require our careful consideration and mature deliberation. Its weal or woe may depend on the action of this meeting.

At an extraordinary session of the Board of Trustees of THE JOURNAL called to meet in Washington city last November, it was determined to submit the question of its removal from Chicago to Washington, to the action of the members of this session.

I would beg the delegates and members of the Association to consider well every side of this question before they commit themselves to a vote, and not act too hastily in the matter. THE JOURNAL has now had its home in Chicago for eight years. Its development and growth has been wonderfully rapid. It has already become the peer of any of the great weeklies of the country and if properly sustained by the profession and wisely and energetically conducted by its managers, it will become the recipient of the best thought of our own country and be the worthy exponent of the American profession. It is free from debt

and has funds sufficient to close the financial year and still leave a satisfactory balance in the treasury. It has been proven that it can be more economically published in Chicago than in Washington. The Board of Trustees several years since solicited and obtained estimates from two or more publishing houses in Philadelphia, Washington, New York and Chicago. These estimates were uniformly highest in Washington and lowest in Chicago.

Chicago is a geographical and railroad centre not excelled in facilities for rapid mail distribution. It is also a great medical and surgical centre and can place at the disposal of THE JOURNAL a wealth of resource, second to no other city in the Union. It is the best place for advertisers to reach the profession in the Mississippi Valley and the great North-west, and if THE JOURNAL should be removed to Washington, it will lose many very lucrative advertisements and will be brought into direct and sharp competition with six important weekly journals, several sustained by large and influential book houses, which occupy the field between Washington and Boston.

Washington is in no sense an important scientific, educational or professional centre; but it is the great centre of American politics, to which everything is made subordinate; and it would be impossible if THE JOURNAL should be published here, to prevent its becoming contaminated by the political air, with which it would be surrounded. Washington has never been a healthy locality for medical journals, for every journal which has been published within its boundaries, has died early from inanition. I do not think that it is a better locality than Chicago that is wanting, but a better Journal than we have.

Let us then as members of a profession engaged in the most beneficent and humane calling known to man, in the language of the immortal Jackson, swear "by the ETERNAL" that THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, wherever it may be located, shall be made and kept equal in excellence with any journal published in the world.

It is now time to enter upon the duties which have called us together. Let us endeavor to discharge them in a spirit of conciliation and justice. Let us act with such prudence and judgment in this meeting as will tend to unite more closely the members of this great National family. Let us not forget how rich an heritage has been bequeathed to us by our predecessors which we should make more valuable and transmit to posterity. Let us indulge the hope that our labors during the present session will not only sustain the advance already made in medical science, but will carry us still further onward in the great road of progress.

THE ADDRESS ON SURGERY.

Delivered at the Forty-second Annual Meeting of the American Medical Association, held at Washington, D.C., May, 1901.

BY JOSEPH M. MATHEWS,

OF LOUISVILLE, KY.

I am familiar with the fact that it is expected that the general address on surgery read to this Association shall be a *résumé* of the advances made in each and every department of the science and art of surgery, since the previous meeting. To have gone over this entire field would have consumed more of your valuable time than you would like to grant, and involved a task too burdensome for me to undertake. I, therefore, determined to select some single subject for my address. I was then confronted by the fact that every single subject of importance would be fully discussed in the section on surgery; hence I was embarrassed in selecting one, for the reason that I wished to edify rather than fatigue you. This, then, was the rub. Having confined myself for fifteen years to a special line of practice, it occurred to me that it would be best to select some subject relating thereto, and give my individual opinion and experience in regard to it. Then, too, I had the consolation of believing that no paper of a similar topic would be read before the Association. I have, therefore, selected as my subject,

STRICTURE OF THE RECTUM—ITS ETIOLOGY, PATHOLOGY, SYMPTOMOLOGY, DIAGNOSIS AND TREATMENT.

I realize, in discussing this subject, I shall take positions contrary to the accepted teachings of the day, but I shall not beg for pardon for so doing. I take it that the one great object of the meetings of this Association is to elucidate and discuss subjects that are in doubt, those that are mooted, not admitted. The caption of my address may sound homely, but the importance of it as a surgical subject should commend the respect and attention of every surgeon here. Its frequency, its terrors, and its dangers, appeal to us for relief.

Etiology.—The following classification of the varieties of stricture of the rectum is given by Dr. Kelsey. I believe that for my purpose it is the best classification, as it embraces the varieties as given and agreed to by many different authors.

Congenital:

1. Complete,
2. Partial.

Acquired:

1. Spasmodic. *a.* Dysenteric.
2. Pressure from without. *b.* Tubercular.
3. Non-venereal. *c.* Inflammatory. *d.* Traumatic.
4. Venereal. *a.* Ulceration (either chancreoid, secondary or tertiary.)
5. Cancer. *b.* Due to unnatural vice. *c.* Neoplastic (gummatous, anorectal syphiloma.)

The first great division, it will be noticed, is congenital and acquired stricture. In writing of, or dealing with stricture, the idea intended to be conveyed is of a pathological change in tissues,

etc., a deviation from the natural brought about by disease; hence I object to the consideration of congenital malformations of the rectum, or to define them under the head of strictures of the same, for the reason that it is misleading to do so. It will be more to the point to call these, atresias of the gut. Therefore, I shall dismiss this part of the division that he has made. Indeed, exception could also be made to the second division of this grand classification, namely, acquired. I am aware of the fact that the term is often used in the sense herein applied, but to my mind a better term or classification could be used. It is very easy to understand how one can acquire a stricture, the result of venery, but it will be difficult to understand how one could acquire a spasmodic or cancerous stricture. But I will adopt, for the sake of discussion, the above classification, leaving out the congenital variety.

1. *Spasm*.—To this form of stricture I shall prefer two objections. First, if it be true that such condition ever exists, which I doubt, then it should not be classed as stricture at all, for the reason that no pathological change is manifest to constitute a stricture, and no treatment could be given it *per se*. In other words, it would be a symptom of some lesion or trouble outside of the one called stricture. Second, I believe that from the anatomical construction of the rectum, it would be utterly impossible for its lumen to be so constricted as to be perceptible as an obstruction, by spasmodic contraction of its muscular fibres. I might add as a third reason, that in all my examinations of this part of the gut, I have never seen a spasmodic contraction that could be called a stricture.

2. *Dysenteric*.—Although it is frequently stated that dysentery is a common cause of stricture of the rectum, I have never seen cases sufficient to convince me of the truth of the statement, indeed that it was a cause at all. I have many times seen patients who gave me a history of having had dysentery and were treated for a long time for the affection, but a close scrutiny of the case revealed the fact that the so called dysentery was caused by an already existing stricture and ulceration, the rule here being reversed.—that dysentery was the result, not the cause. If dysentery really be a cause of stricture of the rectum, how very often we would expect to meet with it in our practice, considering the great number of people who have dysentery, especially in the warmer climates. Again, practitioners of medicine know that ulceration proper very seldom exists in the rectum during or after attacks of dysentery. The sloughing in these cases occurs from the gut above the rectum. I do not deny, but I am not convinced, that ulceration may sometimes be caused by repeated dysenteries or diarrhoea, but my experience has not taught me that they are frequent, by any means. If a long continued irritation is

kept up in the rectum, from any cause, the result would be, of course, an inflammatory exudate, resulting perhaps in ulceration and stricture; but I must confess that in searching for this as a cause, the road to a conclusion has not been plain enough for me to put dysentery in the list as a cause at all for stricture of the rectum. If this disease is a common cause of stricture, as asserted by so many, it occurs to me that the trouble would be often found in the veterans of war. Indeed, I could not imagine a more ideal case for a pension than the existence of stricture of the rectum, the result of a dysentery contracted while in the service. Yet the pension records are singularly silent on this point. At a late meeting of the Louisville Clinical Society, Prof. John A. Ouchterlony, a distinguished pathologist and teacher, in discussing the subject of stricture of the rectum, said:

I call to mind a dead house experience extending over many years. During the war I made post mortem examinations upon hundreds of cases who died of dysentery, the most malignant forms of the disease, as all will attest whose observations extend back to war times, and I cannot remember to have ever seen a stricture of the rectum as a result of dysentery. In the two hospitals, to which I was pathologist, there were eleven hundred and fifty beds, and we sometimes made as many as five or six post-mortems a day. After the close of the war, I was for many years pathologist to the City Hospital, but in all my dead house experience, I never saw a stricture of the rectum caused by dysentery.

These are the remarks of a very close observer, and my experience certainly coincides with his.

3. *Tubercular*.—Since the discovery of the tubercle bacilli, and the demonstrations that convince us of the effect on the tissues, etc., it is self evident that tuberculosis is often met with in the mucous membrane and the structures of the rectum. If stricture and ulceration is the term used, I could make no objection to the classification of tuberculosis as a cause of ulceration. That ulceration frequently results from this diathesis or dyscrasia no one could doubt, but that the coincident stricture follows, as from other well known causes, notably syphilis, I cannot agree. The disposition of tuberculous tissue everywhere is to break down. Before the capacious rectum is filled with tubercular deposit sufficient to stricture it, it will have broken down from ulceration, etc., and it must be by deposition only that we can conceive of stricture from this cause; because cicatrization is so seldom, and so feeble, in these parts that it would be the rarest accident to find it. In no instance have I ever seen a stricture of the bronchi as the result of tuberculosis. There would be just as much reason to expect it here, or indeed more so, than in the rectum.

4. *Inflammatory*.—This term is so broad and comprehensive that we must perforce of reason admit it as a cause of stricture of the gut, indeed as the one grand and common cause; for if stric-

tures exist from whatever cause, be it trauma, pressure, venery, dysentery, cancer, tubercle, syphilis, ulceration, or what not, it is inevitably due to the processes and products of inflammation—in no other way can a stricture be formed. It might be argued that a lesion or wound existing in the bowel by the reparative process heals and leaves cicatricial tissue, and that stricture was the result of the cicatrix, and not to plastic infiltration of the tissue. In answer, I would say that there could have been no cicatrization if there had been no inflammatory process. Hence, inflammation being the cause of the cicatrix, was in truth the cause of the stricture. It is said, "Any severe form of proctitis resulting in ulceration may be a cause of stricture." To this I freely assent, but the most difficult part of the whole matter is to tell the cause of the proctitis, which is inflammation. It is not to the proposition that I object, but to the supposed cause. For instance, in naming several, the following is given as a cause of stricture: "Erosion and ulceration of hæmorrhoidal tumors." Now, in the nature of things, how can this be true? A hæmorrhoid is, in fact, a tumor, and by friction the mucous membrane on the tumor can become ulcerated. Suppose it does, how can that ulceration produce a stricture of the rectum? As we have intimated, strictures may result from two pathological conditions. First, from a deposition of plasma, causing an obstruction, or second, by cicatrization, causing a stricture. Can either of these conditions result from hæmorrhoidal tumors being ulcerated? Certainly not. The inflammatory deposit would only involve the tumor, and a cicatrix on top of a pile would not amount to a stricture.

5. *Traumatism*.—Under this head the authors include ulceration following operations or wounds of the rectum, and cite the surgical operation done for hæmorrhoids and fistula in ano. In all my practice, I have never seen such result follow either operation. I can understand how the cicatrix resulting from the removal of too much skin from the anal region might cause a stricture of the anus. My friend Dr. W. O. Roberts, of Louisville, has told me recently, of operating upon a patient of this kind, the original operation for hæmorrhoids having been done by an inexperienced hand. I cannot understand how a surgeon used to operating in this region, would do an operation that would result in a stricture. But traumatic strictures are, in fact, inflammatory strictures. Inflammation is the result of trauma, so one class would include both. For brevity, this would be best.

6. *Veneral*.—"Without admitting too much," says one author, "it may be safely said that, beyond dispute, there are three forms of well recognized venereal diseases in the rectum, which may result in stricture. These are chancroidal, secondary and tertiary ulcerations, either simple, trau-

matic, or the result of direct inoculation, and an unusual form of tertiary disease of the general nature of gummatous deposit variously described by different authors, and by Fournier as ano-rectal syphiloma." This author leads us to infer that these three venereal causes, namely chancroidal, secondary and tertiary ulcerations, are the most infrequent way that stricture of the rectum can be produced by venery. Allingham reports that out of seventy patients suffering with stricture of the rectum, thirty-five of them had a history of syphilis. I have frequently said that I believe that more than one-half of the strictures met with in the rectum were the result of syphilis. I have often asserted that in no single instance have I ever seen a stricture of the rectum caused by the healing of a soft sore. I do not believe that it can occur. In this opinion I am partially sustained by Allingham, James R. Lane, Alfred Cooper, Coulson, Christopher Heath and others. These three causes are alleged by many to produce their effect by simple trauma or direct inoculation. Neither of these can be true. If so, certainly not one in ten thousand cases. Granting that the soft sore could produce an ulceration that might end in stricture, how, I would ask, can the aforesaid pus get into the rectum? It may have occurred, it is not impossible, but granting that it did by direct contact, I do not believe that it would result in a stricture. Instead of secondary syphilis being an unusual cause of stricture of the rectum, I assert that it is the usual and only form that we find this disease producing or causing stricture of the rectum. Ricord, Fournier, Heath and others believe this, and Mr. Bryant, in his excellent practice on surgery, ascribes these ulcerations and strictures of the rectum as "mainly syphilitic," and says: "Foreign authors describe chancroidal diseases of the rectum, venereal but not syphilitic. In this country it is hardly recognized." I certainly agree with this author. To conclude, if I were asked, what is the prime cause of stricture of the rectum, I would answer *inflammation*. But what causes the inflammation? In many cases I do not know, but ordinarily syphilis, cancer and trauma—if by trauma can be meant a wound or lesion from any or many causes. Outside of the two first named, cancer and syphilis, I am satisfied that no one can tell the cause that originates the stricture. I wish to reiterate, that outside of these two well recognized causes for stricture of the rectum, I am not prepared to admit any other as a well known, recognized, indisputable cause.

Pathology.—In delivering the Bradshaw lecture before the Royal College of Surgeons, London, Mr. Thomas Bryant selected as his subject, "Colotomy." He said:

But as a means for giving relief to patients from chronic intestinal organic ulcerations or obstruction from whatever cause, colotomy was generally, and indeed I may

say is still, too much regarded as a *denier resort*, and as a consequence, it was, as a rule, only carried out when all other measures had been tried and proved to be useless. This position I, in common with some few other surgeons, have, however, never accepted. We have regarded it as the best means the surgeon has at his disposition for the relief of rectal obstruction from cancers and every disease which is not otherwise removable, and experience has proved that life may by it be saved, when the disease is not cancerous, and prolonged even for years when it is so.

Turning to page 605 in Wyeth's Text Book on Surgery, we read: "In stricture of the rectum, when all other measures fail, colotomy is the last resort." Here are two diverse views, by two very distinguished authors. Which is correct? I am decidedly inclined to Dr. Wyeth's opinion (if colotomy is performed at all), and although he has been content with the bare statement, without argument, I shall in a few words give you my reasons for differing from Mr. Bryant, in his statement and proposition. I quite agree with him in the preference given to lumbar over inguinal colotomy, but I beg to differ as to the need for the operation, and base my belief on the pathology of the disease. Instead of admitting his premise that colotomy is called for the relief of rectal inflammation by cancer and other diseases, and should be performed early in the disease, I shall contend that such a procedure is warranted only in the rarest cases, and then as a *denier resort* only, which he denies. My conclusions are based upon an observation of several hundred cases of so-called obstruction of the rectum. I shall not found my objections upon the dangers that attend the operation, although every surgeon will admit that some danger attends it. I recognize the fact that, under antiseptic surgery, the mortality attending these, as well as all other surgical operations, is reduced. However, this admission plays no part in rebutting other arguments that are urged for the operation. I will be permitted to remark that, in my opinion, it has become too much the custom, or fad, to do this operation in cases where there is no possible chance of doing the patient any good. Indeed it has become so common, that the moment cancer of the rectum is diagnosed, colotomy is resorted to. Mr. Bryant states two distinct propositions, namely, "First, the immediate success or failure of the operation turns but little upon the operation itself, if well performed, but upon two main points, the first being the local condition of the bowel above the seat of obstruction, and the second, upon the general condition and age of the patient."

Some surgeon once said, that the reason laparotomies for gunshot wounds showed such a low per cent. of recoveries, was that too many were attempting the operation. Mr. Bryant can very well say that the immediate success or failure of colotomy turns but little upon the operation, if it is well performed. The trouble is that if his

premise be true, that this operation should not be considered as a *denier resort* in stricture of the rectum, but that it should be resorted to early in the disease, and is the best of all procedures, too many men, accepting his dictum as true, will be doing the operation, when less dangerous methods might accomplish the same results. As to his two main points to be considered before doing the operation, first the local condition of the bowel above the seat of obstruction, I take it that he means whether or not the bowel above the seat of obstruction is invaded by the disease, or if, in consequence of the disease below, has suffered. In my opinion it would have been more to the point to have said, the local condition of the bowel both *above* and below the seat of obstruction. He says: "If from procrastination, serious intestinal changes have taken place before relief is present, recovery is hardly to be expected." Now I suppose that the distinguished author refers here to cancer or syphilis as the serious causes of intestinal changes. It is quite agreed that these two diseases account for fully two thirds of the obstructions or strictures of the rectum, which, as Mr. Bryant and others would say, would call for colotomy. Suppose the gut above the stricture was not invaded or changed at all, but that below the stricture, incipient it may be, there is a slight infiltration by cancerous deposit, is the operation justifiable? It certainly cannot agree that it is. It is admitted that a colotomy is a loathing and disgusting thing. Patients with cancer of the rectum live from three to six years. Many in my practice have lived five years after the disease was first observed. Why subject these people to such an operation during the incipency of the disease, when it does not stop it? Again, are we quite certain that there is an infallible sign of cancer? In quite a number of cases I have taken specimens from rectal growths, had them examined by microscopists, and pronounced cancer, whose subsequent history revealed the fact that it was not cancer at all. Then, too, in the early stages of cancer, there is not sufficient clinical evidence to base an opinion upon. Certainly for a benign and incipient stricture, or obstruction, if you please, in this locality, colotomy would not be advised.

Again, if the disease be cancerous, in its incipency, or otherwise, can the operation of colotomy cure it? It might be, as Mr. Bryant suggests, the operation could be done much more successfully while the general health is in good condition, but it is not whether one can perform colotomy successfully or not, the prime question is, what good will it do? A surgeon may do a beautiful operation for stone in the bladder and get the stone, but the patient dies. How then, I would ask, can the establishing of an artificial anus in the side, in any way cure or arrest the in-

roads of cancer in the rectum. If, then, it is granted that the disease being constitutional will go on regardless of the opening in the side, I would ask can the colotomy prolong life of the cancerous patient? In no way possible can it do so, but one, that is by preventing one source of irritation, namely, the passage of feces over the cancerous mass. The argument would be, the more irritation, the more deposit.

In my opinion, this is of very little importance, or consideration in cancer of the rectum. Malignant growths increase by an inherent power, a deposition, infiltration, etc., intrinsic, not extrinsic. They will exist in the rectum a long time, acquiring a great size, involving, perhaps, the whole circumference of the gut before the mucous membrane is ulcerated, notwithstanding this "great irritation" is constantly kept up. I dare say if a cancer of the same kind and proportion, in the same character of subject, could be watched each day, in one colotomy had been performed, the other without, that no difference could be observed in the rate of progress that was being made. I am forced to this belief after an observation of many years, covering many cases. As I have before stated, my patients have generally lived from four to six years with cancer of the rectum, without colotomy. Do they live any longer with colotomy? In other words, can any one say, because, colotomy being performed, a patient lives four or six years, that the colotomy was the cause of prolonging his life?

Again, it is claimed that by colotomy much of the pain is the rectum is relieved, in that the feces having been directed from their natural course. In some instances this may be true, but the rule will not hold good in all. I have known patients to suffer equally as much with pain after, as before the operation, nor is it always true that the feces are diverted from the natural channel. Much discomfort is often complained of by the patient, after a colotomy, from the feces lodging in the mass, or strictured surface.

In a paper read by Mr. Jessop, on the treatment of cancer of the rectum, at the Leeds meeting of the British Medical Association, he said: "In cancer of the rectum, the constriction in the majority of cases can be got over for a time, by injections, the introduction of the finger, or bougies, the use of laxatives and the like." This has certainly been my observation. Indeed I have seen many cases where the patient never complained of even constipation or obstruction. Add to this that many patients of the kind complain of but little, if any pain, especially if the growth is situated above the sphincter muscle, it lessens the cases materially which would call for colotomy.

I cannot agree with Mr. Bryant in his statement that the operation is demanded for the purpose of relieving the local distress, admitting, as

he does, that when the disease is in the lower part of the rectum that obstruction seldom occurs. I have seven cases of cancer of the rectum now under observation, and in but one is pain a factor at all. Admitting that pain is a prominent symptom, colotomy does not bring that radical relief which would justify its being done. We have in opium a remedy which will quiet pain effectually, and if the argument be used that we would make an habitué of the patient, I would remark, what is the difference if he is to die so soon? As I have observed, pain in cancer is inherent, caused by the local affection of the nerves, and is not controlled by extraneous circumstances. Hence, of what account is opening the gut at a distant point, if pain is not a great factor in the disease? If, in answer, it is said that it prevents the irritation and pain caused by the passage of the feces, I would answer that in many cases this does not increase the pain, and if it does, dilatation will materially prevent it. I saw, this day, in consultation, a lady whose lower rectum, including buttocks, labia, etc., were involved, the gut for six inches tightly strictured, and when asked how much pain she suffered, answered, "Oh, very little," and said that the fecal discharges caused her no trouble.

If, as some would have us believe, colotomy would prevent the extension of the disease, and its consequences, such as involvement of the bladder, vagina, etc., I would ask how is colotomy to prevent it? It is not the passage of fecal matter over the affected parts that causes this result, but rather the nature of the disease to infiltrate, and break down the tissue. If a cancerous growth is situated above the sphincter muscle, its tendency is to extend upwards, and in this event pain is not great, unless some other organs are affected. It is not uncommon that patients come to my office to consult me for some trivial rectal affection and I find, upon examination, a cancerous mass, extending all around the rectum, pain being scarcely a symptom in these cases. Of what value would colotomy be here? Hence I am forced to the conclusions that the operation is not warrantable simply because cancer is found in the rectum, either in an incipient or confirmed state; nor for the relief of pain simply, unless other complications exist, for we have medicines that will relieve pain; nor to prevent invasions by the disease, because it would fail of its purpose. Infiltration and pathological change cannot be overcome by colotomy. Nor for obstruction or fear of obstruction in the lower rectum, because, as Mr. Jessop says, this obstruction seldom takes place, and if it does, it can be relieved by dilatation and other methods. Lastly, I do not believe that colotomy should ever be done for the obstruction of the rectum by cancer, save, perhaps, in a few exceptional cases, and then only as a *dernier resort*. Yet in every instance before

the operation is done, the nature of it and its consequence should be fully explained to the patient, with the assurance that it cannot possibly effect a cure. It is a well recognized fact that colotomy is advised and practiced by many, for other ulcerations and constrictions of the rectum, beside those of a cancerous nature. Except under certain conditions, I shall object to this procedure with just as much emphasis as to the operation in malignant stricture.

I have stated, in this article, that I do not hold to the theory of chancreoidal ulceration, as so vehemently advocated by Zeigler, Mason, Kelsey, Gosselin and others. My reasons have already been given, but I do hold that syphilis is responsible for more than one-half the cases of stricture of the rectum, and in the manner I have described. But to do a colotomy simply because a patient has a syphilitic stricture of the rectum, is, I believe, unjustifiable. As a proposition, then, I shall maintain that where a syphilitic stricture or strictures exist in the rectum, located within four inches of the external sphincter muscle, colotomy should not be done. In supporting this statement, I desire to say that in my opinion, a stricture located within the distance named, can be treated more successfully by other methods.

Before leaving the subject of colotomy, as one of, if not the most important of all methods of treatment for stricture of the rectum, from whatever cause, I beg to call to mind that the statistics of Erckelen carefully compiled in 1884, and shown by Treves that 38 in every 100 cases of lumbar, and 46 in every 100 cases of iliac colotomy died within twenty-one days after the operation. This statement speaks for itself. Stricture from benign causes located within the distance that I have named, should be dealt with in a similar way.

Symptoms.—The early symptoms of stricture in the rectum are very obscure and confusing. Indeed no stricture exists at all in the pathological changes going on in the gut which conduce to this state. The great trouble is that the early symptoms are so masked or entirely *nil*, that no attention is paid to them by the patient, that when he is forced to consult a physician a very decided stricture may exist. The changes made manifest in the rectum are those of inflammation and, if from cancer, the condition of the blood vessels, and the gradual deposit of the morbid material, together with infiltration of the tissue, goes on so slowly and insidiously, that for a long time there are really no symptoms. I have seen many cases where the first symptom noticed was a so-called constipation, obstipation would be a better word, and upon the introduction of the finger a tight constriction could be felt. This may apply to any form of stricture. I have under observation now three cases of this kind. The first symptoms of stricture then are not the

discharge of bloody pus, etc., indicative of ulceration, that some describe. Therefore, I must differ from those who place the symptoms of ulceration first, and those of constriction afterward. Ulceration cannot take place, together with the symptoms incident thereto, a discharge of blood, pus or muco purulent, until the changes of inflammation have been such that the mucous membrane and sub-mucous tissues have undergone that change which constitutes ulceration. When this latter condition is established, we have the characteristic discharges—diarrhea, flatus, the muco-purulent discharge, or rather a muco-bloody discharge first, succeeded eventually by a purulent discharge, and alternating diarrhea and constipation. The bearing down sensation, together with tenesmus, a reflected pain to the back and down the thighs, an irritation of the kidneys and bladder, and uncomfortable feeling always about the rectum. A passage of small bits, or tape-like actions, are all indications of the disease. I am persuaded that oftentimes stricture is diagnosed from this characteristic tape-like action, when in reality the moulding is done by the sphincter muscle in an irritable state, and that no stricture in reality exists. I am satisfied, too, that many cases of so called chronic constipation are due to a narrowing of the lumen of the gut from this cause. This has occurred so often in my practice that I am now in the habit of examining the rectum in every case of chronic constipation. This same rule holds good in cases of supposed dysentery, for, as I have observed, dysentery is but one of the symptoms of stricture, and caused by it.

I have had but two cases of acute obstruction caused by the chronic condition of the stricture. One in the case of a young lady who failed to report to me as often as necessary for a dilatation of the stricture (she would not consent to an operation) and during a summer outing took sick and died from an acute obstruction. The other was a young married woman, in the practice of one of our local physicians. An operation with the knife relieved her. Acute obstruction, as the first symptom of stricture, I have never seen, although I have examined a number of patients who complained of constipation only, who upon being examined, showed a decided stricture that the smallest finger could not pass. In one instance I found a close stricture at the entrance of the sigmoid flexure. It is truly wonderful to see patients who have strictures of the smallest calibre, who seem to enjoy perfect health, and whose physical proportions and development are not hurt in the least. It must not be forgotten, however, that these are dangerous conditions and constantly imperil the life of the patient.

Diagnosis.—When the stricture is within four inches of the sphincter muscle, it is easily diagnosed, be it malignant, benign or syphilitic—the

finger will detect it. It is a very different matter, however, to determine its character, and yet, to a certain extent, the treatment depends upon it. I desire to quote from Kelsey the following statement:

There is an old and deeply rooted idea in the minds of the profession, that a stricture of the rectum must be either cancerous or syphilitic—an idea founded on error and capable of doing much harm and injustice to innocent people. Again and again I have been able to give great comfort to women suffering from this disease by denying the correctness of this idea, and in my own practice, the fact that a stricture is not cancerous adds little weight to the idea that it may be syphilitic.

This is so diametrically opposed to my views and observations that I desire to say that, in my opinion, fully sixty per cent. of the strictures of the rectum are due to syphilis. Not venereal in the sense that many would have us believe, namely: by the infection of the rectum by cancerous pus, or by direct contact, but as a secondary deposit, the result of constitutional disease. There are but few authors to day that deny this fact, but in admitting it, class these as exceptional cases. By a late estimate it is calculated that five million people in the United States are subjects of constitutional syphilis. If it is admitted that one single case of stricture of the rectum can result from this constitutional disease, it admits the argument. Then taking into consideration the great number affected with it, is it any wonder that we should have the per cent. named as suffering from this manifestation in the rectum? Mr. Allingham, in tabulating his cases of stricture, says: "Thus out of the total number of 99 patients, 52 or more were syphilitic."

As a means of diagnosis, the clinical history and observation of the case has much to do with forming a correct opinion. If it is ascertained that the patient has constitutional syphilis, I would consider that it was a strong point gained. I do not wish to be understood as saying that in every case where both syphilis and stricture exist, that the latter was caused by the former, but undoubtedly in the vast majority of cases this is true. Indeed, so firm am I in this belief, that if it is a question between cancer or no cancer, and it is decided that it is not malignant, 99 out of every 100 cases will prove to be syphilitic; for the reason that stricture, the result of benign ulceration, does not resemble in the least stricture from malignant deposition. To the contrary, syphilitic stricture does, to a degree, in its pathology, resemble malignant growths. To be plainer, malignant disease, and syphilitic disease, invade the rectum as a deposit, infiltration of the sub-mucous tissues, etc. Ulceration here is secondary to the deposit caused by the friction of the passage of feces, or the breaking down of the tissue, the result of the disease *per se*. Benign ulceration begins with the damage done to the mucous membrane, and the plastic infiltration is secondary to

it, the reverse of both the malignant and specific disease.

Again, as a diagnostic symptom, the touch reveals a great deal. Allingham says: "There is something peculiar about the feeling of cancer, which the operator's finger rarely mistakes even for simple indurated ulceration." This is the fact, yet if I was called on to describe it, I could not. It is said by many authors that the peculiar smell or odor of cancer is pathognomonic. I am certain that I have seen many cancers that did not evidence this peculiar odor. Great stress is also laid on the disposition of malignant growths to bleed, especially when touched or handled. I am just as sure that I have seen many cases of cancer that had no such disposition. The swollen or enlarged glands in the inguinal region cannot be taken as a positive sign or indication of cancer in the rectum, from the fact that they are swollen in many cases of benign ulceration and inflammation. I will again state that pain, in my opinion, is made too great a symptom of cancer. It depends altogether upon circumstances whether it exists to any degree or not. In cancer the nodular form of the mass is more apparent than in any other trouble. In syphilis, the induration is more even and extends with more regularity, and after a time is of a fibrous character and is so indicated to the touch. In simple ulceration, the stricture is apt to be annular.

As a method of diagnosis, I object to the use of rectal bougies, either metal, soft, or hard rubber, to which so many authors call attention. They are exceedingly dangerous, and accomplish no earthly good. I have known two patients killed by the attempt to introduce the common hard rubber English bougie within a stricture of the rectum. The common seat of stricture is within reach of the finger. It is the rarest thing that one is ever found in the movable gut. Granting that one exists there, if there is not a total obstruction, what is the use of an exploration with a dangerous instrument, when the finding of the stricture, or the supposed finding of it would result in no good. A stricture located in the movable gut cannot be dilated. If it be total occlusion or obstruction, it calls for very different treatment from this.

Treatment.—In considering the treatment of this very formidable disease, I shall adhere in the strictest sense to the pathological condition, namely, a stricture. This entirely rules out the treatment of proctitis, or the subsequent ulceration, which is one cause of stricture, and brings us directly to the means of treating that which is the result of said causes. It must be granted that many times ulcerations, which would eventuate in stricture, are cured before that condition results. This cannot hold good in cancer. Can it in syphilis? I doubt it. In the great majority of cases, we are confronted at the onset with stric-

ture, not with the ulceration, so insidious is the disease. The methods practiced to-day for treating stricture of the rectum are:

1. Dilatation.
2. Incision
3. Electrolysis, and raclage.
4. Excision.
5. Colotomy.

Of course, under the division I have made, we rule out general treatment.

Dilatation.—Kelsey in speaking of dilatation, says.

"By dilatation I mean gradual stretching, not forcible divulsion," and adds that the latter is seldom applicable. I must dissent to these views. The gradual dilatation of stricture is objectionable, for the reason that by this form of repeated irritation, more plasma is thrown out and the stricture surface increases. It may be true that some temporary relief is afforded, but upon the contraction of the tissue, which is sure to take place, we have lost more than we have gained. I do not hold to the view that by the passing of bougies through the stricture surface absorption of the tissue is caused, I believe that the converse is true. Why forcible divulsion is seldom applicable in these cases, I cannot understand. If a fibrous stricture exists, I am sure that forcible divulsion is the best method. In other words, we do, in a few minutes, by immediate dilatation, what it would take weeks to accomplish by gradual dilatation. The fear, in the past, has been hæmorrhage in this operation. To-day we do not fear it, because we understand how to control it. Therefore, I would put but little stress, or no stress at all, upon treating stricture, of whatever kind, by bougies. In fibrous stricture it would do no good; in the malignant one, it would be dangerous. I have abandoned their use altogether.

In 1878 I read a paper before the Kentucky State Medical Society, in which I reported a case of close stricture at the entrance of the sigmoid flexure. The plan adopted was to break the sphincter muscle, introduce the hand and arm into the rectum, and reaching the stricture, which barely admitted my index finger, I made a cone of my four fingers and forcibly pushed them through the stricture. It gave way before them, and although great shock supervened, the recovery from immediate danger was effectual. I am satisfied that a more perfect and radical relief was obtained than if I had done colotomy. Gradual dilatation here was out of the question. I am very positive then in saying that if dilatation of a stricture of the rectum is decided upon, let it be a forcible and radical one.

Incision.—I am very partial to incision, or incisions, for the relief of stricture of the rectum. Of the two operations recommended, internal and external posterior linear proctotomy, I much prefer the internal. It is urged for the external,

which consists of not only going through the stricture surface, but also in dividing the sphincter muscle, that it is all important to get the necessary drainage. I do not think so, and if I did, I believe the ill-effects of dividing the sphincters outweigh the matter of drainage. I cannot believe that the internal incision is as dangerous as it is represented to be by some authors. My plan is to introduce a three or four valve speculum, and, after dilating sufficiently for the purpose, a long sharp knife is used to divide the constrictions of fibrous tissue, down to a healthy base—not only in the median line, but in several places around the circumference of the gut. I then place a tampon, through which I have inserted a metallic tube for drainage, and the escape of gases. This tampon is aseptic, and usually dusted with powdered persulphate of iron. On the fourth day it is removed and the rectum irrigated with a mercuric solution. If the operation is done effectually, I have never seen the necessity of employing the bougies afterward, for the purpose of dilatation. Patients are averse to their use, and they do not accomplish the good claimed for them. My objection to the external operation, although I have practiced it often, is that to divide the sphincters when all the tissues are in a diseased condition invites non-union, and incontinence is nearly certain to follow. The suggestion of Weir, to confine the incision to the stricture and then to drain the incision by a tube brought out through the skin, at the tip of the coccyx, I do not think will accomplish the purpose in many cases; besides, it leaves a channel which may not heal. To divide the sphincters and then employ three or four deep provisional wire sutures between the anus and the strictures, leaving them loose and stuffing the incision with charpie, after the manner of Kelsey, I think unwise and unsurgical. It is said that one great danger of the operation is septic peri-proctitis, but under antiseptic precautions, the danger, in my opinion, is reduced to a minimum. In one case of malignant disease, in which I did the external operation, rapid sepsis took place, and the patient died in twenty-four hours. I do not think either the internal or external operation should be done for malignant growths, unless total, or nearly total, occlusion has taken place. In all cases of non-malignant stricture, syphilitic or simple, either the internal linear proctotomy of the French surgeons, or the external operation as practiced by many, is far more preferable to excision, or colotomy.

Electrolysis.—It does appear that where we can so effectually go through a stricture by linear proctotomy at one sitting, that it would be useless to attempt so slow a process as electrolysis. After a careful review of the subject, I cannot believe that any benefit obtained is brought about by the dilatation from the electrodes used, as

suggested by some. If there be a benefit, in fact, it must be attributed rather to what is claimed for it—partial destruction of tissue by cauterization. To claim radical cures by this method, I must admit, seems untheoretical, if not unsurgical, and yet Dr. Newman and others report many cases of stricture cured by this method. In a paper read before this Association and published in THE JOURNAL, he makes the following conclusion:

1. Electrolysis in the treatment of stricture of the rectum is not a panacea; on the contrary failures may happen, and probably will, if the stricture is due to carcinoma. 2. Electrolysis will give improvement to the stricture when all other methods have failed. 3. Electrolysis will cure a certain percentage of cases, without relapse, and without the necessity of an after treatment or using bougies. 4. The best agents for a cure are through the fibrous inflammatory stricture.

Having no personal experience with this method of treating a stricture of the rectum, I am not prepared either to advocate it or disprove the statements made.

Excision.—I think a better term to employ here would be extirpation. Excision of a stricture of the rectum conveys but a little idea of the operation. I cannot appreciate the idea of excising a benign stricture, not from any serious doubts as to whether it could be done or not, or any dangers attending the operation, but there are methods so much simpler in their nature for the relief of benign strictures, that I cannot conceive of a surgeon attempting its excision.

Extirpation of the rectum for malignant disease I believe to be an ideal operation. Between the plan of the German surgeons of removing the entire rectum up to the sigmoid flexure, and the English surgeons of restricting the operation to a very limited extent, I believe that a middle ground can be established and practiced, based upon a true pathology. It is an axiom in surgery that in operating for cancer, the whole growth must be removed, together with the glands that are involved. Let us take this axiom as our guide in rectal surgery. If the growth extends beyond the point where it is prudent to operate, it is best not to attempt its removal, except, perhaps, for total obstruction, not with any idea of cure. Cripps makes the point that the operation is of doubtful propriety when the disease involves the upper part of the recto-vaginal section, where it is covered with peritoneum. I do not consider this injunction as meaning that it is so dangerous to open the peritoneum, but that this membrane being involved in the disease, renders the operation useless. If, however, there is no fear of the invasion of the peritoneum, an admirable operation is afforded us by Kraske's suggestion, enabling us to remove much of the length of the rectum. The chief argument in favor of his operation is that the entire length of the rectum can be removed, without disturbing the

sphincter muscles. In continence of feces, the result of injury to these muscles, is the one great objection to any other mode of operating.

Kraske's operation is admirably suited to cancerous stricture. It consists in resecting the diseased part, through an opening made at the left side of the sacrum. This operation, of course, is only applicable in a certain class of cases. For instance, if the sigmoid flexure is involved, it would be of no use. If the stricture is low down, it can be divided with a knife. According to his method, the soft parts are divided in the median line from the second sacral vertebra to the anus. The muscular attachments to the sacrum are divided as far as the edge of the opening on the left side. The coccyx is removed, the attachments of the two sacro-sciatic ligaments to the sacrum are cut, and the soft parts drawn to the left side. If still more room is necessary, it may be gained by removing a part of the lower left side of the sacrum. If the bone be divided on a line, beginning on the left edge, at the level of the three posterior sacral foramen, and running in a curve concave to the left, through the lower border of the three posterior sacral foramen and through the fourth to the left lower border of the sacrum, the more important nerves are not injured and the sacral canal is not opened. In this way, the lower part of the rectum, as far as the sigmoid flexure, may be removed. It will be found in this operation, that the dissection is a very difficult one.

Alexander modified this operation, the chief points being that he excised the coccyx and all of the sacrum necessary to a certain limit. Experimenting with the two, I much prefer Kraske's original operation. I have removed as much as five inches of the rectum, by simply removing the coccyx, making a deep and long dorsal incision, and then practicing a thorough dissection of the gut. The one great object of both of these operations is to keep the sphincter muscles and anus intact. It is true, however, that in some cases the cicatrization is sufficient to establish partial control at least of the actions after the removal of the muscles. This was beautifully illustrated in a case of extirpation which I recently did for cancer. The patient was a man about 60 years of age. The growth extended completely around the gut, beginning at the anus and extending up the rectum for fully five inches. The tissues surrounding the rectum were involved to the extent of three inches. Both sphincters were embraced in the disease. A deep dorsal incision was made through the sphincters and tissues to the sacrum, and brought out over the coccyx. The incision was then made completely around the whole diseased structure, extending from the coccyx, around through the perineum. The gut and sphincters were then carefully dissected out. The vessels were tied as they were cut, drainage

tubes placed, and the wound dressed antiseptically. I did not do as the German surgeons suggest, draw down the end of the rectum to the skin, attach it by a row of sutures, nor did I do as Allingham and Kripps advise, stitch the gut lightly to the skin, and leave the wound to close by granulation. In lieu of both, I left the wound just as I made it, and made no attempt to either bring the mucous membrane down or to stitch it. When the wound had filled up and healed, the cicatrization afforded him protection against any sudden evacuation of the bowels. I am more and more persuaded that where there is a possibility of removing the entire malignant growth from the rectum, excision is far more preferable to colotomy. Excision would remove the disease, thereby having some grounds to hope that it will not reappear. By colotomy we simply palliate the symptoms, leaving the disease in its ravages.

Colotomy.—In a paper read before the Ninth International Medical Congress, which convened in this city in 1887, I took exception to colotomy as a means of treating cancer of the rectum. In that paper I said:

It is after a careful survey of all the reasons advanced by those who advocate colotomy, in cases of cancer of the rectum, that I am constrained to differ from them and to say that I do not believe that the operation is justified in these cases, except under the rarest circumstances if at all.

I am still of the same opinion. Too many people are being subjected to this horrible and disgusting operation, that could be benefited equally as much, by simpler means. The operation in itself promises but little. Kelsey says:

It is the common doctrine taught, that it is to prolong life by the relief of pain, the prevention of obstruction, and in retarding the growth of cancerous disease.

To these statements I cannot give my full approval. First, that to prolong life by the relief of pain I answer, in the majority of cases that have come under my observation, and they have been many, there has not been much pain complained of. Indeed, it has not been a factor. A young lady just sent to me from the South, with a pronounced cancer of the rectum, says she has never suffered any pain. This is simply repeating what many have said to me. If this, then, be the reason assigned for the operation, these cases would be ruled out, and they constitute the majority. But suppose that pain exists, does colotomy relieve it? It may in some cases, but I am certain that in many it does not. As I have said in this article, pain is within the growth itself, by the involvement of the nerves. Surely colotomy could not relieve it. It is likely true that the feces passing over the growth may irritate it to a certain extent, but my experience has taught me that if the sphincter muscles are not involved, there is but little pain, and if they are

involved, scraping the mass out, according to the Germans, will relieve it, equally as well as colotomy would. Again, it must be admitted that after colotomy is done, there is no absolute certainty that some of the feces will not pass down into the rectum.

Second, that it prevents obstruction. It will be admitted that the greater number of cancers are located in the lower or fixed part of the rectum. It is a recognized fact, too, that total obstruction from fecal impaction rarely takes place, because it is the disposition of malignant disease to break down after a certain stage. But suppose it does not, and a stricture, total, if you please, results, to cut through it, divide it, or resect it, would be better than to do colotomy. The first two will promise equally as much, and the last much more. I have never seen a total obstruction by feces in a cancerous stricture. I have known total obstruction to occur by the closure of a stricture. We have means of eradicating this by the three methods mentioned. They are much simpler than colotomy, why not do them?

Third, that it retards the growth of cancerous disease. Neither can I subscribe to this proposition. How the establishing of an artificial opening in the loin or groin materially retards the growth in the rectum, I cannot understand. I know that it is used as an argument that the stoppage of the feces over the growth would, to a degree, stop the growth. This is utterly fallacious. The cancer persists in its progressive course of infiltration, ulceration, etc., with as much rapidity after colotomy is performed. Correct statistics of the condition will verify my statement. Admitting that there was truth in the assertion, patients who suffer with cancer to that degree, or extent, requiring colotomy, are not anxious to have their lives prolonged. As a last argument, it is said that colotomy substitutes a painless death for one of great agony. This statement cannot be borne out by facts. Patients who have malignant disease of the rectum usually die of a slow and gradual form of peritonitis. I have witnessed a number of such deaths, and they are usually painless. In what way colotomy can substitute a painless death, granting that such a condition exists, I cannot understand. It would appear that they would die very much the same way, whether colotomy is done or not. So I am forced to conclude that neither one nor all of the so-called arguments in favor of doing colotomy, instead of other methods, for cancerous stricture, can be substantiated in fact. If I were asked, when is colotomy justified in cancer of the rectum, I would answer, rarely, if at all. But if there be total obstruction of the sigmoid flexure from a cancerous mass, and if for any special reason we wish to prolong life a few days, then I believe colotomy would be justifiable. I know that this is a radical view to take of the case, and I also

recognize that the great majority of surgeons will differ from me, but my conclusions have been formed after a careful investigation of the subject.

But to proceed. Is colotomy to be recommended as a procedure in the treatment of stricture of the rectum? I unhesitatingly answer, yes. Whenever a stricture other than malignant, especially when caused by syphilis, is located in the movable part of the gut, or in the sigmoid flexure, either causing total obstruction or about to cause it, colotomy should be done. If I am asked why, in this instance, and not in cancerous stricture, I would answer, in this we prolong life indefinitely. I see no reason why one should not live many years after the operation done for this condition. A fibrous stricture in the locality named would likely cause death by occlusion, if let alone. It is beyond reach for dilatation, division or excision. There is nothing in the stricture *per se* to cause death, only in the manner mentioned. It acts as a foreign body, causing obstruction. It can never be reabsorbed. It cannot cause death by infection of the body. Having blocked the channel, we open a gate-way above for the escape of feces, and life is prolonged indefinitely. To do the operation for cancerous stricture, the disease is neither stayed nor cured. The patient dies and the friends ask, why you did so formidable and disgusting an operation, when you knew that death would so soon ensue. To the contrary, in benign or syphilitic strictures, the patient will live to thank you for doing the colotomy. If, then, it is decided to do colotomy, which of the two operations is preferable, the lumbar or extra-peritoneal, or iliac, or intra-peritoneal? I think the anatomical phrase used in designating the two should decide it. An operation extra-peritoneal is certain to be preferred to one that is intra peritoneal.

I am cognizant of all that is said in regard to the perfect safety of opening the peritoneum under aseptic precautions. Nevertheless, it cannot be gainsaid that it is more dangerous to open the peritoneum than not to open it. I know, too, it is asserted that in doing a lumbar operation, the peritoneum is often opened. This has not been the case in my experience, and in Mr. Bryant's 170 cases of lumbar colotomy, the peritoneal cavity was opened but twice. This disproves the assertion. It is urged in favor of the iliac operation, that by it there can be no possibility of the surgeon mistaking the small intestines, duodenum, or stomach, for the large intestine. Just as well say that it is dangerous to attempt to ligate internal hemorrhoids, because there is a possibility of including the prostate gland. A surgeon that could not recognize the stomach from the colon, ought not to attempt a colotomy. If the operation is done for the condition that I have named, namely cancerous stricture or obstruction in the

sigmoid flexure, the lumbar operation is also preferable for the reason that it is a greater distance from the diseased part and not so apt to be embraced by it.

I have not the time or disposition to argue the pros and cons of this much mooted question. I think Mr. Bryant has met all the objections against the lumbar operation, and I quite agree with him when he says: "Iliac colotomy is not yet proved to be superior to the lumbar operation."

LECTURES.

THE CHEMICAL FACTORS IN THE CAUSATION OF DISEASE.

A Course of Three Lectures delivered at the Post-Graduate Medical School of Chicago, March 26, 27 and 28, 1891.

BY VICTOR C. VAUGHAN, M.D., Ph.D.,
OF ANN ARBOR, MICH.

PROFESSOR OF HYGIENE AND PHYSIOLOGICAL CHEMISTRY AND DIRECTOR OF THE HYGIENIC LABORATORY IN MICHIGAN UNIVERSITY.

(Continued from page 618.)

LECTURE II. THE BACTERIAL POISONS OF SOME OF THE INFECTIOUS DISEASES.

An exact classification of the chemical factors in the causation of the infectious diseases can probably not be made at present. We know of two chemically distinct classes, one of which contains substances which combine with acids, forming chemical salts, and which in this respect at least correspond with the inorganic and vegetable bases. The members of this class are designated as ptomaines, a name suggested by the Italian toxicologist, Salmi, and derived from the Greek word *πτωμα*, meaning a cadaver. A ptomaine may be defined as a chemical compound which is basic in character and which is formed by the action of bacteria on organic matter. On account of the basic properties, in which they resemble the vegetable alkaloids, ptomaines may be called putrefactive alkaloids. They have also been called animal alkaloids, but this is a misnomer, because in the first place some of them are formed in the putrefaction of vegetable matter; and in the second place, the term "animal alkaloid" is more properly restricted to the leucomaines, those basic substances which result from tissue metabolism in the body. While some of the ptomaines are highly poisonous, this is not an essential property, and others are wholly inert. Indeed, the greater number of those which have been isolated up to the present time do not, when employed in single doses, produce any apparently harmful effects. Briege restricts the term ptomaine to the non-poisonous basic products, and designates the poisonous ones as "toxines." This is a classification, however, which seems to be of questionable utility. It is not always easy to say

just what substances are poisonous and what are not. The poisonous action of a substance depends upon the conditions under which, and the time during which, it is administered. Thirty grains of quinine may be taken by a healthy man during twenty-four hours without any appreciable ill effect, yet few of us would be willing to admit that the administration of this amount of quinine daily for three months would be wise or altogether free from injury. In the same manner the administration of a given quantity of a putrefactive alkaloid to a dog or guinea-pig in a single dose may do no harm, while the daily production of the same substance in the intestine of a man and its absorption continued through weeks and possibly months, may be of marked detriment to the health. We do not as yet know enough about the physiological or toxicological action of the putrefactive alkaloids to render the classification proposed by Brieger worthy of general adoption.

All ptomaines contain nitrogen as an essential part of their basic character. In this they resemble the vegetable alkaloids. Some of them contain oxygen, while others do not. The latter correspond to the volatile vegetable alkaloids, nicotine and coniine, and the former correspond to the fixed alkaloids.

Since all putrefaction is due to the action of bacteria, it follows that all ptomaines result from the growth of these microorganisms. The kind of ptomaine formed will depend upon the individual bacterium engaged in its production, the nature of the material being acted upon, and the condition under which the putrefaction goes on, such as the temperature, amount of oxygen present, and the duration of the process.

A second class of the chemical factors in the causation of the infectious diseases embraces the so-called poisonous albumins. In 1886, Mitchell and Reichert published the results of their investigations into the nature of the venom of serpents, from which they concluded that the poisonous constituents are peptones and globulins. Of the latter they reported the presence of three varieties, each of which is toxic in its action. Although it had been known before this that the injection of any considerable amount of artificially prepared peptone directly into the blood is followed by markedly deleterious effects, this was the first demonstration of the possession of characteristic toxicity by any of the proteids, and from the report of Mitchell and Reichert we may date all modern studies, at least, of the poisonous albumins.

In 1887, Sewall found that tolerance to the venom of the rattle-snake could be established in pigeons by the inoculation of a very small quantity and gradually increasing the amount. In this manner a pigeon was found to bear without ill effect seven times the amount ordinarily fatal to the same animals. The immunity thus ob-

tained was observed to gradually diminish after the discontinuance of the inoculation. However, after five months, while the larger amounts reached in the last injections proved fatal, the ordinarily fatal dose was without effect.

Salmon and Smith protected pigeons against the germ of hog cholera by previous injections with cultures of the same organism which had been sterilized by exposure to a temperature of from 58° to 60° C. for one hour. However, since these cultures contained one or more ptomaines, as well as the poisonous albumins, it could not be, at that time at least, said to which of these constituents the immunity was due.

To Christinas, I believe, is due the credit of first showing the presence of active proteids in bacterial cultures. In 1888, this investigator obtained from cultures of the staphylococcus pyogenes aureus a proteid body which, when injected into the anterior chamber of the eye or under the skin, caused suppuration.

We will now give our attention to the chemical poisons, both the ptomaines and the albumins, of some of the infectious diseases, and in doing this we will illustrate and substantiate the statements made in the preceding lecture.

Anthrax.—The definition of an infectious disease, as we have given it, is well illustrated by the facts which have been learned concerning the causation of anthrax, which has, probably, been more thoroughly studied than any other infectious disease. Kausch taught that this disease has its origin in paralysis of the nerves of respiration. Upon the cause of this paralysis he gave us no information. Delafond thought that anthrax has its origin in the influence of the chemical composition of the soil, affecting the food of animals and leading to abnormal nutrition. The investigations of Gerlach, in 1845, demonstrated the contagious nature of the disease, which was emphasized by Heusinger in 1850 and accepted by Virchow in 1855. However, as early as 1849, Pollender found numerous rod-like microorganisms in the blood of animals with the disease. This observation was confirmed by Branel, who produced the disease in healthy animals by inoculations with matter taken from a pustule on a sick horse. Attempts were made to ridicule the idea that these germs might be the cause of the disease, and it was said that the bodies seen were only fine shreds of fibrin or blood crystals. Some claimed that the rod-like organisms reported were due to defects in the glass, while others claimed that the defects existed in the eye of the observer, and others still suggested that the defects might be found back of the eye and in the brain. But in 1863, Davaine showed that these little bodies must have some causal relation to the disease, inasmuch as his experiments proved that inoculation of healthy animals with the blood of those sick with anthrax produced the disease only when

taken at a time when the blood contained these organisms. He also demonstrated beyond any question that these rod-like bodies are bacteria, capable of growth and multiplication. The conclusions of this investigator were combated by many; but Pasteur, Koch, Bollinger, De Barry and others studied the morphology and life history of these organisms, and then came the brilliant results of Pasteur and Koch in securing protection against inoculation anthrax by the vaccination of healthy animals with the modified germ and subsequent inoculation with the virulent form. Now, the bacillus anthracis is known in every bacteriological laboratory, and by inoculation with it the disease is communicated at will to susceptible animals. But here the question arose, How do these bacilli produce anthrax? and in answer to this question the various theories which we have mentioned were proposed.

The first successful attempt to study the chemical poisons of anthrax was made by Hoffa, who obtained from pure cultures of the bacillus small quantities of a ptomaine which, when injected under the skin of animals produces the symptoms of the disease and death. This substance causes at first increased respiration and action of the heart, then the respirations become deep, slow and irregular. The temperature falls below the normal; the pupils are dilated, and a bloody diarrhoea sets in. On section the heart is found contracted, the blood dark, and ecchymoses are observed on the pericardium and peritoneum. Hoffa names his poison anthracin.

It has been said that Hoffa's work was the first successful attempt to study the chemical poisons of anthrax. However, his results cannot be considered altogether satisfactory. The small amount of the basic substance which he obtained rendered it highly probable that in the case of a germ so virulent as that of anthrax there must be other chemical poisons produced. This supposition has been confirmed by the labors of Hankin who, in 1889, while at work in Koch's laboratory, prepared from cultures of the bacillus anthracis an albumose which when employed in comparatively large amount proved fatal to animals, but when used in very small quantity gave immunity against subsequent inoculations with the living germ. Unfortunately Hankin does not mention the symptoms induced by toxic doses of this substance. Whether or not the albumose of Hankin contains in *statu nascendi* the base of Hoffa, and owes its poisonous properties to the same, has not been determined. There is yet a promising field for research in the chemistry of this disease.

Asiatic Cholera.—There are good reasons, apart from experimental evidence, for believing that the comma bacillus of Koch produces its ill effects by the elaboration of chemical poisons. This germ is not a blood parasite. It grows only in

the intestine, and the symptoms of the disease and death must result from the absorption of its poisonous products. In confirmation of this statement, experiment has shown that this is one of the most active, chemically, of all known pathogenic germs.

In the first place, Bitter has shown that the comma bacillus produces in meat-peptone cultures a peptonizing ferment, which remains active after the organism has been destroyed. Like similar chemical ferments it converts an indefinite amount of coagulated albumin into peptone. It is more active in alkaline, than in acid solutions, thus resembling pancreatin more than pepsin. This resemblance to pancreatin is further demonstrated by the fact that its activity is increased by the presence of certain chemicals, such as sodium carbonate and sodium salicylate. That a diastatic ferment is also produced by the growth of the bacillus was indicated, in the experiments of Bitter, by the development of an acid in nutrient solutions containing starch paste. However, all attempts to isolate the diastatic ferment were unsuccessful. A temperature of 60° C. destroys or greatly decreases the activity of ptyalin, and this seems to be true also of the diastatic ferment produced by the comma bacillus. But the formation of an acid from the starch presupposes that the starch is first converted into a soluble form.

Rietsch believes that the destructive changes observed in the intestines in cholera are due to the action of the peptonizing ferment.

Cantani injected sterilized cultures of the comma bacillus into the peritoneal cavities of small dogs and observed after from one-quarter to one-half hour the following symptoms: Great weakness, tremor of the muscles, drooping of the head, prostration, convulsive contractions of the posterior extremities, repeated vomiting and cold head and extremities. After two hours these symptoms began to abate, and after twenty-four hours recovery seemed complete. Control experiments with the same amounts of uninfected beef-tea were made with negative results. The cultures used were three days old when sterilized. Older cultures seemed less poisonous and a high or prolonged heat in sterilization decreased the toxicity of the fluid. From these facts Cantani concluded that the poisonous principle is volatile, but the effect of high or prolonged heat in diminishing the toxicity was more probably due to its destructive effect on the poisonous proteids.

Brieger succeeded in isolating from cultures of the comma bacillus in meat broth two basic substances which he considers the specific poisons of cholera. One of these, found in the mercuric chloride precipitate, is a diamine, resembling trimethylenediamine. It produces muscular tremor and heavy cramps. In the mercury filtrate was found another poison, which, in mice, produced a lethargic condition; the respiration and heart's

action became slow, and the temperature sank, so that the animal felt cold. In some instances there was a bloody diarrhoea.

Later Brieger and Fränkel have obtained a cholera-albumin which proves fatal to guinea-pigs after two or three days, but is without effect upon rabbits.

More recently Winter and Lesage treat a bouillon culture of the cholera germ with sulphuric acid, dissolve the precipitate in an alkaline medium, reprecipitate with acid, and redissolve in ether, which on evaporation leaves oily drops which, on cooling, form a yellow mass of the appearance of a fat. This substance is insoluble in water and acids, soluble in alkalis and ether. It melts at 50° C., and does not lose its virulence on being boiled with alcohol rendered feebly alkaline. The virulence of a culture and the amount of this substance contained therein are in direct proportion to each other.

Small doses of this substance (one milligram to 100 grams of body weight of the animal) in feebly alkaline solution introduced into the stomachs of guinea-pigs cause, as a rule, within from four to six hours, a chill, and death after twenty-four hours. With larger doses the temperature falls after from one-half to one hour, and death results within from twelve to twenty hours. Smaller doses cause a less marked reaction and the animal recovers within twenty-four hours. If killed within this time the animal shows a choleraic condition. Rabbits succumb only after repeated subcutaneous injections. The substance can be extracted from the muscles, liver, kidneys and urine of the poisoned animals. This substance can also be obtained from cultures of a cholera infantum germ. The fact that this poison belongs neither to the ptomaines or albumins is of interest.

Cholera Infantum.—The fact that Booker, Escherich and other investigators have failed to find any one germ constantly present in the bowels or stools of children suffering from summer diarrhoea was mentioned in the preceding lecture. Notwithstanding this, the fact that chemical poisons are concerned in the production of these diarrhoeas has been abundantly demonstrated. In the first place the symptoms of the choleraic form of these diarrhoeas are so very similar to those induced by a number of gastro-intestinal irritants, which at the same time depress the nerve centres, that the suggestion that the disease might be due to chemical poisons has been favorably received by the profession. The poisonous substance first found by the writer in cheese and afterwards in ice-cream, milk and various milk preparations, and which is known as tyrotoxin, induces symptoms which cannot be distinguished from those of choleraiform diarrhoea in infants. Moreover, the post-mortem appearances are very much alike, if not identical, and the poison has been

found in a sample of milk, a part of which had been given to a child not more than two hours before the first symptoms of a violent attack of the disease manifested themselves.

Tyrotoxin however, is only one of the poisons which may appear in milk and milk products, or may be formed in the intestines of the infant and cause an exhausting diarrhoea. I have recently isolated from samples of poisonous cheese, in which tyrotoxin could not be detected, a poisonous albumin.

I have also isolated from pure cultures of the germs, x, a, and A of Booker's list of summer diarrhoea microorganisms, three poisonous bodies, small quantities of which injected under the skin of kittens and puppies cause retching, vomiting, purging, collapse and death. Ten milligrams of the dried proteid from "a" killed a large guinea-pig within twelve hours, and a smaller amount proved fatal, in other experiments, after a longer time. These poisons differ from one another, more or less, in their physical and chemical properties, but all produce the above mentioned symptoms. It may be that a more exact study of the effects induced will enable us to distinguish, in this way, one from the other. Evidently, here are three germs differing from one another morphologically sufficiently to be classified as different species, but belonging chemically and toxicologically to the same group. How many more of the long list of bacteria found by Booker, Escherich and others in the study of these diseases remains to be ascertained. There is no reason, however, for supposing that in taking three of these at random, I have hit upon the only toxicogenic ones.

The fact that Baginsky's cholera infantum germ produces a poisonous albumin was referred to in the first lecture; also the formation of a choleraic poison by the germ of Lesage has been mentioned in discussing the chemical poisons of Asiatic cholera.

The prevention of the summer diarrhoeas of infancy becomes a more difficult task than those who believe that a single microorganism is concerned in their causation admit. All bacteria which are capable of growth and reproduction within the intestines of the infant, and of the production of chemical poisons during their development, must be excluded. The treatment of the same diseases will not be wholly successful until we know how to antidote these poisons. To accomplish these ends will probably require many years of research and observation by our profession. However, if this be the right line, let us follow it, realizing that our successors will profit by our mistakes, and render our partial successes more successful.

Diphtheria.—Roux and Tersin rendered cultures of Löffler's bacillus of diphtheria sterile by filtration through porcelain and injected thirty-five cubic centimeters of the filtrate into the ab-

dominal cavity of guinea-pigs. No immediate effects were observed, but after two or three days, the animals refused to eat, passed bloody urine, showed muscular weakness in the posterior extremities, manifested marked irregularity in respiration and died after from five to six days. Section showed marked renal hyperemia and a serous exudation in the pleura. In cases of less acute intoxication, paralysis of certain groups of muscles become apparent.

The cultures first employed were seven days old. Older cultures (six weeks) contain more of the poison, and the symptoms appear within a few hours after the injection. In cultures especially rich in the poison, a small amount (from 0.2 to 2.0 cc.) injected under the skin suffice to induce the symptoms. The place of injection becomes oedematous, the respiration rapid, and death results as quickly as after inoculation with the germ. Mice and rats are markedly insusceptible, but succumb to large doses.

The action of this poison was found to be much lessened by continued exposure to a temperature of only 58°. These investigators believed that this poison belonged to the group of enzymes.

Brieger and Fränkel have continued the study of the chemical poison of the Löffler bacillus. These investigators find that this poison can be heated to 50° in the presence of an excess of hydrochloric acid without being destroyed, and they conclude from this that the substance cannot be an enzyme or ferment. The poison is precipitated from the culture, after sterilization by filtration through porcelain, by absolute alcohol, slightly acidified with acetic acid. It forms a snow-white, amorphous mass. It stands very closely related to serum albumin. It may also be precipitated by saturation with ammonium sulphate, and can be purified by removing the sulphate by dialysis. This reaction distinguishes it from the peptones. In small doses (two and one half milligrams per kilogram body weight), injected into the blood-vessels, it causes death, not like other poisons, immediately, but after days, weeks or months, with the formation of abscesses and necrotic tissue at the point of injection, with progressive emaciation and paralysis. Brieger and Fränkel propose for this and similar bodies the name "toxalbumin." As was stated in the first lecture, these studies leave no room for us to doubt that the Löffler bacillus is a cause of diphtheria. The chemical poisons of Prudden's streptococcus and of the germ found by Klein in the diphtheria of some of the lower animals, have not been investigated.

Suppuration.—The fact that a pus producing chemical poison was found in cultures of the staphylococcus pyogenes aureus has been already noted. In addition much interesting work on the poisons of suppuration has been done. That the ptomaines, cadaverine and putrescine, of Brieger,

when injected under the skin in sterile solutions, cause abscesses, has been known for some years. It has been shown that sterilized cultures of a number of different germs produce suppuration. Thus, Büchner showed that sterilized cultures of the bacillus of Friedlander contains pyogenic substances, and when injected into man in very dilute solution produce an elevation of temperature. In view of the fact that so much has been said about the wonderful effect of small doses of the so-called cure for tuberculosis proposed by Koch, the following account of an experiment made upon himself and reported by Büchner early in 1890, may be of interest: Five tenths of a cubic centimeter of a sterilized very dilute emulsion of Friedlander's bacillus was injected under the skin of the forearm, after it had been found that 500 times this quantity, reckoned per kilogram of body weight, caused no local irritation or suppuration in a rabbit. One and one-half hour after the injection sharp pain extended along the arm to the axilla. One-half hour later there was a chill followed by a fever which reached a maximum of 36.6° in the axilla five hours after the injection. At the same time the pulse arose to 108. On the following day there were well marked erysipelatous swelling and redness extending over an area larger than a saucer about the place of inoculation, and there was marked redness along the lymphatics of the arm. On the third day all these symptoms disappeared.

Büchner has shown that the cells of seventeen different species of bacteria contain pyogenic substances. The cells may be boiled for hours, their substance dissolved in dilute alkali and precipitated by acid without losing its pyogenic properties. It should be understood, however, in this case that the active substance is contained within the bacterial cell, and this leads us to distinguish between the chemical poisons which arise from bacterial activity and are found in solution in cultures, and those which reside within the cell and form an integral part of the same. Büchner finds this active substance within the cell to be proteid in character. It gives the biuret, Millon's and xanthoprotein reactions. Before the substance can cause suppuration within the body it is most likely necessary for the bacterial cells to suffer disintegration. It is hardly necessary to add that the pus formed by this bacterial proteid is germ-free.

Typhoid Fever.—The poisons of this disease are both basic and proteid, though those belonging to the latter group seem to be the more virulent.

In 1885 Brieger obtained from pure cultures of the Eberth bacillus a ptomaine, which produced in guinea-pigs a slight flow of the saliva, increased frequency of respiration, dilatation of the pupils, profuse diarrhoea, paralysis and death within twenty-four to forty-eight hours. Post-mortem examination showed the heart in systole, the

lungs hyperemic and the intestines contracted and pale. Brieger was at first inclined to regard this as the specific poison of typhoid fever and named it "typhotoxine." However, he obtained with this substance no elevation of temperature.

In 1887 Novy and the writer obtained from cultures of a germ found in drinking water which had been the supply of many persons who had typhoid fever, an extract which, when injected under the skin of cats, caused an elevation in the temperature of from two to four and one-half degrees.

In 1889 the writer obtained, from mixed cultures made from typhoid stools, a small amount of a basic substance which caused, in the lower animals, an elevation of temperature accompanied by profuse diarrhoea.

Brieger and Fränkel obtained, from cultures of the Eberth bacillus, a poisonous albumin, but have reported no particulars concerning its action. The writer has two germs, obtained from drinking water supposed to have caused typhoid fever, and which, after having been kept for some days at a fever temperature, give all the reactions which have hitherto been supposed to be characteristic of the Eberth bacillus. From pure cultures of each of these he has isolated highly poisonous proteids, which, in dogs, cause a chill, followed by marked elevation of temperature. These poisons are soluble in water, from which they are not precipitated by heat or nitric acid, singly or combined. They are precipitated by saturating the aqueous solution with ammonium sulphate, and are not, therefore, peptones. They are not precipitated by carbonic acid gas, or by sodium sulphate to saturation, and this excludes them from the class of globulins. The aqueous solutions respond to the xanthoprotein and biuret reactions. Chemically I can so far distinguish no difference between the poisonous albumins produced by the two germs, but physiologically there is a marked difference. That from bacillus A produces paralysis of the voluntary muscles, which is preceded in some animals by most violent convulsive movements. With the proteid of bacillus B neither the convulsions nor the muscular paralysis has been observed. The animal seems to die from gradual failure of the heart. However, these poisons demand a much more extensive and exhaustive study than has yet been made. It will be seen from what has been said, that the chemistry of typhoid fever promises to be both fertile and interesting in results.

Tetanus.—Brieger has obtained from the mixed cultures of the germs of Nicolaier and Rosenbach, four poisonous substances. The first, tetanine, which rapidly decomposes in acid solutions, but is stable in the presence of free alkali, produces tetanus in mice when injected in quantities of only a few milligrams. The second, tetanotoxine, produces tremor, followed by severe

convulsions. The third, to which no name has been given, causes tetanus, accompanied by a free flow of the saliva and tears. The fourth, spasmotoxine, produces heavy convulsions.

Later, the same investigator extracted tetanine from an amputated arm of a man with tetanus. This is of special importance, since it answers the assertion made by Baumgarten, that there is no proof that the poisons which have been obtained from artificial cultures, are formed within the body of man.

From pure cultures of the tetanus bacillus of Kitasato, Brieger and Fränkel have isolated a poisonous proteid, and with cultures of another bacillus, Tizzoni and Cantani have been equally successful. These investigations leave us without cause to doubt that the convulsions of traumatic tetanus are due to one or more spinal poisons, and the causal relation of a given bacillus is determined not by its morphological characteristics, but by its capability of producing a chemical substance which has a definite toxicological effect.

Tuberculosis.—Whatever may be the ultimate verdict concerning the curative properties of Koch's tuberculin, its employment has made us familiar with the action of the chemical products of the bacillus tuberculosis on man. Unfortunately, Koch has given us but little information concerning the nature of his tuberculin, and the little which he has given us has been to some extent misleading. I would not imply that he has intentionally been misleading. Indeed, I believe that such was not his intention. He speaks of the agent as an extract of a pure culture of the bacillus tuberculosis with 50 per cent. glycerine. Now, chemists who have been at work with bacterial poisons, distinguish between bacterial products and the contents of the bacterial cells. One would infer from Koch's statements that tuberculin is prepared by extracting the bacterial cells with 50 per cent. glycerine, and that the bacterial products are not present. But, as has been shown by Hueppe and Schall, the proteids of the cells of the bacillus tuberculosis cannot be extracted with 50 per cent. glycerine. Moreover, the same investigators have prepared a fluid identical in physical properties, in chemical reactions, and in its effects on animals, with Koch's fluid, by each of the three following methods:

1. Cultures of the bacillus are filtered, sterilized by heat and concentrated.

2. The supernatant, fluid portion of the culture is decanted from the mass of germs at the bottom of the flask, and then concentrated.

3. The culture is freed from germs by filtration through a Chamberland filter and concentrated.

These fluids contain, 1, the constituents of the nutritive medium which have not been altered by the growth of the germ, such as glycerine, albu-

mins, albumoses and peptones; 2, the bacterial products, which may possibly belong to the ptomaines, the bacterial albumins or albumoses and bacterial ferments; and 3, any constituents of dead, broken-down bacilli which may have passed into solution. To which of these constituents the action of the fluid is due has not been positively determined. However, from the similarity in the action of this fluid with that of the bacterial products of other germs, we seem justified in assuming that these constitute the active principle.

As early as 1888, Hammerschlag found a poisonous protein among the products of the growth of this germ.

Recently Zuelzer has reported the isolation of a poisonous ptomaine from agar cultures of the bacillus tuberculosis. He says that the injection of 1 centigram or less of this substance subcutaneously in rabbits or guinea pigs causes, after from three to five minutes, increased frequency of respiration (to 180 per minute?) and an elevation of temperature of from 0.5° to 1° . He also reports marked protrusion of the bulb as a constant symptom; the eyes become very bright and the pupils are dilated. From two to three centigrams suffice to kill rabbits, death occurring in from two to four days. The place of injection is reddened and hemorrhagic spots are formed in the mucous membrane of the stomach and small intestines. In two instances from 15 to 20 cc. of clear fluid were found in the peritoneal cavity.

(To be concluded.)

MEDICAL PROGRESS.

Therapeutics and Pharmacology.

TREATMENT OF BED-SORE.—BILLROTH recommends that the part should be bathed with vinegar or lemon juice as soon as erythema appears. Excoriations should be touched with nitrate of silver and the part dressed with simple cerate, or soap plaster spread upon linen or soft leather. When gangrene occurs the surface should be covered with a disinfectant, such as chlorinated water. Carbolic acid should be avoided, because of its liability to cause poisoning. Energetic internal measures should be employed, to strengthen and build up the system, such as wine, acid drinks, quinine and musk.—*L'Union Médicale*.

Medicine.

DETERMINATION OF THE LOWER BORDER OF THE LIVER.—VERSTRALTEN (*Centralblatt für Klin. Med.*) points out how difficult it is in many cases to outline the surface, and particularly to determine the exact position of its lower border. This he thinks is easier by auscultation than by any other method; taking advantage of the ex-

cellent conducting power of the liver, the stethoscope is placed over the heart and then gradually moved downward and to the right. The point at which the heart sounds are no longer heard marks the lower border of the organ. A source of error is contracted abdominal walls; they should be relaxed as far as possible, if necessary, by placing the patient in a sitting posture.

Surgery.

TEN YEARS' EXPERIENCE OF GASTRIC SURGERY.—DR. TORRAS has made a study of the statistics of the resection of the pylorus during the years from 1880 to 1890. From this it appears that in 1880 there was one extirpation followed by death. In 1881, out of 20 in whom the section of the pylorus was performed, there were 15 deaths and 5 cures. In 1882, the numbers stood, as out of 16 cases: 13 deaths and 3 cures; in 1883, 13 cases, 7 deaths and 6 cures; in 1884, 5 deaths and 3 cures; in 1885, 5 cases, 3 deaths and 2 cures; in 1886, 3 cases, 1 death and 2 cures; in 1887, 2 cases, 2 cures; in 1888, 1 case, 1 cure; in 1889, 1 case, 1 cure; in 1890, 2 cases, 2 cures.

In reviewing these statistics Dr. Torras observes that the surgical enthusiasm which led a man so eminent as Billroth to sanction this operation has evidently decreased, till, in 1889, only one operation of the kind was performed, and two in 1890. This proves that the results have not corresponded to the hopes conceived, and that such an operation is very rarely indicated in cancer of the stomach. Dr. Torras details a case of exploratory laparotomy performed by Dr. Fargas in a woman of 52, who had for several months suffered from vomiting and pain in the gastric region. In this situation a moveable tumor could be felt, about the size of an orange, which was supposed to be malignant, and to be attached to the gastro-colic epiploon. On opening the abdominal wall, it was found to be a carcinoma of the head of the pancreas, adhering to the duodenum and pylorus. Under these conditions, Dr. Fargas did not venture to attempt removal, but confined himself to cauterize with the thermocautery some points of the bleeding surface of the tumor, and to close the incision with sutures. The outer wound healed in ten days, and the patient felt better for a month after, when she died in a cachectic condition.

Though most of those stated to be cured by the operation have survived above five years, yet none of them can be regarded as really out of danger from the disease. Dr. Torras would confine the operation of gastrotomy to cases in which digital or instrumental dilatation might be practiced for simple stenosis of the pylorus, or for contraction of the orifice from cicatrices or fibrous tumors, or for the extraction of foreign bodies from the stomach.

SATURDAY, MAY 9, 1891.

SURGICAL TREATMENT OF GENERAL
PARALYSIS.

The possibility of curing general paralysis by trephining the skull is again coming into prominence. Two years ago DR. SHAW, of London, performed the first operation of this kind, which was practically a success. He reasoned that all the symptoms in general paralysis seemed to indicate an irritative inflammatory process in the upper layers of the convolutions. An operation would produce an alteration in the morbid process; on the theory of nerve stretching he proposed to give the brain at this point more space to expand, and relieve itself of the increased arterial pressure, which the sphygmograph indicated as one of the early conditions of this disease. He hoped by relieving the fluid pressure to stimulate some new nutritive processes.

The patient upon whom the operation was performed was in the second stage of the disease. He had delusions of grandeur, affection of speech, exaggerated reflexes, unsteady gait and retention of urine. Convulsive attacks followed, with periods of loss of sensation, difficulty in swallowing and talking, and rapidly approaching dementia. The trephine was applied on the right side of the skull, over the central sulcus, two inches outside of the longitudinal fissure. The patient improved to such an extent that he was discharged as recovered.

From post-mortem appearances in such cases both atrophy of the brain and increase of brain fluids are found. It is not known whether this condition comes from pressure of brain fluid or

whether the fluid collects on account of brain shrinking. The extreme bulging of the dura in this case seemed to show that the first theory was correct. By removing a portion of the bone, and corresponding meninges of the brain, not only would the existing fluid be let out, but a permanent contact would be established between the secreted fluid and the under surface of the scalp-flap, to the absorbent of which was entrusted its future removal.

The second case was operated on by DR. BATTY TUKE. It was farther advanced and more hopeless. A large button of bone was taken out, and the patient was more sane and improved in every way for some time; finally the old symptoms returned, and he was taken to DR. CLOUSTON'S asylum at Edinburgh, and at present he is hopelessly demented. DRS. TUKE and CLOUSTON both considered that the operation was fully justified, and that the modifications and improvements in the symptoms were hopeful signs of what might be expected in more recent cases.

Several criticisms have been made on the theories of this operation. It is asserted that the paralysis, loss of power of talking, attacks of stupidity, etc., are not due to fluid pressure, and that the excess of fluid is only a secondary and compensating process. Also that holes in the skull cannot relieve the pressure on the convolutions. TUKE asserts that obstructed lymph makes its way very imperfectly by natural channels to the pia-matral space and becomes diffused through the tissues, injuring and displacing cell and fibre, and impairing their functional activity, while the operation, by permitting a healthy action of the lymphatics and blood-vessels, stays the process of sclerosis.

The criticism of this view is that only in the second stage of this disease is there any extraordinary development of the lymph connective system of the brain, with degeneration and disappearance of nerve elements, the axis cylinders of which are denuded: that the first stage is one of true degeneration due to acute interstitial changes, that are similar to senile atrophy. That the excess of fluid in the second stage is of secondary importance, and is the only stage when an operation can be expected to be of any value on this theory, while in fact the case has passed all possibility of cure in this stage. The first stage is the only period that any operation can be justifi-

fied, but at this time no lymph has been formed, and no benefit can be expected on the pressure theory. The critics affirm that any change which may follow this operation is due to a natural remission in the disease.

From these theories and criticisms there are many reasons for expecting some startling developments along this new line of brain surgery. The general hopelessness of these cases, and inability of remedies to even stay the progress of the disease, would seem to justify the surgeon in experiments, which cannot alter the final issue of the case, under any circumstances. The reckless use of powerful remedies experimentally and theoretically is common in nearly all cases, and the surgeon is equally justified in attempting means that give promise of relief. These two cases will arouse new interest in this disease, and suggest theories of pathology and treatment that would have been impossible a few years ago.

THE VALUE OF KOCH'S TUBERCULIN.

The therapeutical results obtained by tuberculin may be summarized in two statements: 1. With the exception of certain forms to be specified hereafter, the agent exerts a specific effect on all tubercular lesions, by starting an inflammatory process in and around the tubercular tissue, which tends to cure the disease. 2. This reparative change has NOT proceeded up to the actual cure in the majority of cases hitherto treated. The exceptions not influenced by tuberculin are old lesions in a state of caseation, a fact already pointed out by KOCH in his first communication, but also fresh miliary eruptions, attention to which latter important observation has been called by VIRCHOW and other pathologists. The inability of tuberculin to affect fresh miliary tubercles or to prevent their dissemination, and the frequent cessation of its curative influence before the infiltration has completely disappeared, are at present the main obstacles to success with this treatment. But in order to review what the agent can do and has done, it is necessary to consider the various tubercular localizations separately.

In *lupus*, with scarcely an exception, the agent has produced an improvement which, competent observers claim, cannot be obtained by any other means within the same time. This improvement

can proceed up to absolute cure of the disease, at least for the time being. Thus, of the later authors, DOUTRELEPONT states that of thirty-one cases of *lupus* four were completely cured, and all the others were in a state of marked improvement. But in the majority of cases the improvement ceases before the entire patch is healed, while in others where a smooth cicatrix has resulted, nodules can still be felt under the skin and —on the cessation of the treatment—these give rise to fresh manifestations of the disease. Yet most of the writers admit that they could not have benefited their patients to the same extent within the same time by any other means.

In tuberculosis of the mucous membranes and of the larynx especially, perhaps the most brilliant results have been accomplished with tuberculin. Numerous cases have been placed on record, in which the ulcers healed completely under the eyes of the observer, even when the accompanying pulmonary lesion was not benefited to the same extent. It has often been noticed that on mucous surfaces, and especially in the larynx, fresh nodules and even minute ulcers appear in the vicinity of the preëxisting lesion under tuberculin treatment. In one of such instances FLATAU has proven by histological examination (presence of bacilli) that the nodule was a true tubercle. It is an open question whether these "new" lesions are the result of preëxisting bacilli, the presence of which is made manifest by the tuberculin influence, or whether they indicate really a dissemination of the virus. At any rate, they disappear readily under the continuance of the treatment, differing in this respect from fresh eruptions in internal organs. A few instances of laryngeal tuberculosis (and also diseases of other mucous surfaces) have been reported without benefit from tuberculin, but as a rule this agent has cured the tubercular localization in these parts with a rapidity not equaled by any other means at our command. It is not possible to prove its relative efficacy by statistics as yet. In the official report to the German Government on the efficacy of KOCH's remedy 108 cases of laryngeal tuberculosis are mentioned, of which seventy-one had been more or less improved. But this report includes only experiences of from two to six weeks, and that during the time when most observers were only learning the mode of employment of the substance. More definite

statements can be obtained from the separate publications in periodic literature, but in most cases the number of cases is not fully stated.

In *phthisis* satisfactory results have been obtained, as a rule, only in *incipient* cases, *i. e.*, of short duration, weeks or months, infiltration limited in extent, no cavities and no continuous fever. KOCH himself cured his first two patients, and repeated examination has confirmed their continued good health during the last three to four months. The majority of incipient consumptives are reported as improved, at least subjectively, by most of the authors. Gain in strength, cessation of night-sweats and of evening rise of temperature, and diminution of cough, indicate a favorable change which, under the observation of GUTTMANN, is said to have occurred in 41 of 51 cases of incipient *phthisis*. The improving patients do not always gain in weight, although this often occurs. Evidently the reparative influence is counterbalanced by the increased tissue consumption during the febrile reaction, especially if the latter be intense. But a consumptive cannot be said to be cured until all cough has ceased, and no sputum containing bacilli can be obtained. A perfect cure does not necessarily imply that all abnormal percussion and auscultatory sounds have disappeared. For where there was any extensive consolidation of lung tissue we can neither expect normal breathing sound nor resonance of normal lung tissue. There will always remain a shrinkage of the involved part of the lung. But applying all reasonable criticism, we can still say that not a few cases of completely cured incipient *phthisis* are now on record. Perhaps the most favorable figures are claimed by STRICKER, who speaks of eight absolute cures among nine young soldiers with incipient *phthisis*, whilst amongst forty-seven soldiers, whose pulmonary trouble was more advanced, four could be considered completely well at the end of treatment. While many observers speak nearly as highly as STRICKER of their experience in incipient *phthisis*, especially in private and in sanitarium practice, others like SCHULTZE report but little success, but such pessimistic reports are decidedly in the minority. Yet it must be admitted that a few instances even of beginning *phthisis* get worse under the treatment, whether in consequence of or notwithstanding tuberculin, is an open question. Any continuous febrile move-

ment produced by tuberculin can be considered a contraindication against its further use.

The *more advanced phthisis* is the less can be expected of KOCH's remedy. Cases of diffuse infiltration, extensive cavities, or rapid course towards the worse have but rarely been arrested in their progress, and occasionally been injured by tuberculin. Still, with some discretion in their selection, and the cautious use of minute initial doses, they need not all be excluded absolutely from the treatment, for in a fair number of instances at least subjective amelioration has been noted. As KOCH suggested in his first note, the influence of tuberculin should be aided by all measures known to benefit such patients. The most promising results have been obtained by SONNENBURG in KOCH's hospital wards by the surgical treatment of cavities combined with tuberculin injections. Only those cases were selected in which the cavities were limited to the upper lobe of one lung; the patients being yet in a state of moderate vigor. After cutting down to the fascia with the resection of a piece of the first rib, a trocar was plunged into the cavity, the wound enlarged with the thermo cautery and a strip of iodoform gauze inserted. SONNENBURG considers the operation easy and comparatively safe when there are adhesions between the two layers of pleura, and but little more serious when the pleural space still exists over the region of the cavity. He reported five cases, one of which was cured inside of four weeks while two more were on the road to recovery. One died, but from the disease, and not in consequence of the operation, while the fifth had but been operated upon just before publication. Others have since repeated the operation, but their results are not yet known.

In *pleurisy of tubercular origin* a rapid absorption of the effusion has been observed in most instances, but the pulmonary lesion itself has not been invariably benefited, its course being influenced in about the same manner and with the variable results as observed in similar instances without pleural complication.

MULTIPLE BIRTHS. — An English physician writes to the *British Medical Journal* of a woman who had twins five times, triplets once, and single children four times.

"IN SIMPLICI SALUS."

HIPPOCRATES proclaimed that "accurate observation of facts, and correct generalization from them, forms the only rational basis of medicine," and so we are taught to-day. To discover truth in science, the most learned will admit, is very often difficult, but in no science is it more difficult than in medicine. Independent of the common defects of medical evidence, our self-interest, our self-esteem, our prejudices, our likes and dislikes, and not infrequently our ignorance, only too often hide the truth from our view, and we ascribe too much to art, and too little to the operations of nature. Thus the mass of testimony is most with art, and, although we believe we are right in our reasoning, we only pursue the old, time-honored course that has been instilled into our minds through training and education. The best and safest practitioner is he who knows when to abstain from acting as well as when to act; in other words, who has learned when and to what extent the case can be left to the salutary processes of nature. The tendency to recovery which manifests itself under different modes of treatment, and even in spite of opposite modes, has induced in some minds a degree of skepticism as to the utility of any remedies. That the opposite error to that of mischievous or meddling activity may likewise be easily carried far is at once apparent. It does not follow because the majority of diseases, such as continued fevers and acute affections generally get well, with or without the administration of medicine, that therefore the disease should be abandoned to what Cullen calls the "*vis medicatrix nature*."

A knowledge of the circumstances upon which health depends is one of the most important parts of the moral and intellectual education of the true physician. The essentials necessary to the attainment of health are:

1. The inheritance of a healthy constitution.
2. Pure atmosphere and water.
3. Wholesome food in quantity and quality.
4. Freedom from contagious and infectious diseases.

Either of these primitive essentials of health is controlled but little, if any, by the individual efforts of man. To medical science solely must mankind look for the foundation rock from whence the principles governing these essentials of nature's law are to be revealed by virtue of in-

telligent, progressive, active, zealous, and truly conscientious physicians, who will, sooner or later, succeed in educating the legislator to understand and realize the fact paramount, that only through the State or municipal government can we ever hope to see mankind enjoy these blessings. Nature puts into our hands the means of preserving health, and this gift involves responsibility. Health will be counted among those talents for the use of which we are to answer to our Creator, and it is our duty to become fully acquainted with the laws which regulate and govern it.

Experience teaches that disease, as well as health, is controlled by nature, that her laws must be consulted if we would practice successfully. But alas! how often do we find—even in this most enlightened age of science—the truth as expressed by the late PROF. CHAPMAN, "That many physicians are given to profound thought, and possess extensive knowledge, united with sterling honesty, being by nature endowed with the highest order of talents, and yet be wanting in good common sense." The most experienced, close observing, earnest searchers after truth in nature's operations, most skillful and best physicians, hesitate above all things to give large quantities of medicine, and proclaim the best way to help the invalid to health is simply to "assist nature." The writings of Drs. Benjamin Rush, Shippen, Chapman, Radcliffe, Bostwick, Dumoulin, and Oliver Wendell Holmes, Sir Astley Cooper, Sir Wm. Gull, and numerous other shining lights are too well known to need reiteration, but are simply called to mind as evidence that the more matured minds in the profession are guided by the light of nature's *in simplici salus*.

EDITORIAL NOTES.

ENDOCARDITIS DURING MEASLES.—Mr. J. H. Hutchinson submitted a contribution to the Royal Medical and Chirurgical Society of London, at its meeting of April 14, 1891, in which a connection was held to subsist between measles and endocarditis, four cases being cited in which the heart affection developed during the course of the acute exanthematous disease. The opinions of the medical gentlemen present were divided on the subject, some declaring that heretofore

unexplainable cases might find solution through the possible influence of the specific poisons producing the acute febrile diseases of childhood. The cases presented by N. W. Hutchinson, though few, were yet sustained, in a measure, by the post-mortem appearances of other cases with like characteristics.

This connection—or, as we should more readily believe, coincidence—has been noted before. We quote Garrod, as follows: "Dr. Sansom is of opinion that the importance of measles as a predisposing cause of endocarditis has not been sufficiently taken into account, and he is inclined to assign to that fever a share in the production of articular rheumatism also. He has, moreover, recorded a case in which chorea, associated with pericarditis and endocarditis, developed during convalescence from an attack of measles."

SECOND CHILDHOOD.—This is often spoken of as a condition into which those of advanced life enter. The mind, disposition, and actions become child-like, until finally the evening of existence becomes no less lightsome and blank to sterner realities than maintained at the dawn of life. However that may be, we have in medicine occasional evidences which, if they do not point to a secondary physical childhood—so to speak—yet are sufficiently interesting to have note. Among these points of interest may be mentioned a case of scarlet fever occurring recently in a woman 59 years of age, and a case of whooping-cough in a man aged 84.

A PRAISEWORTHY RELIEF ORGANIZATION.—The Society for Relief of Widows and Orphans of Medical Men (British), of which Sir James Paget is President, is active in the work towards which its title points. Examples of signal benefit, in the operations of such societies, are not at all few, and, like all such acts of honorable charity, the result is of a two-fold nature.

INEBRIATISM A DISEASE.—As emphasizing the trend of professional opinion in the direction of the morbidity of inebriatism may be mentioned the proposals embodied in the President's Address before the Society for the Study of Inebriety, of London, as follows:

1. "In all criminal trials in which the alleged criminal act has been committed by the accused when under the influence of liquor, or has been committed by an inebriate, there should be an

investigation into the previous medical history of the prisoner. There should also be an inquiry into the family history, so as to elucidate the heredity with special reference to inebriety, insanity, and other neurotic affections, syphilis and gout. This twofold inquiry should be entrusted either to a medical expert, or to a mixed committee composed of a legal and medical expert acting conjointly. The object of this investigation is to ascertain how far the accused has been cognizant of his alleged criminal offence, as to whether he was competent to discern its consequences, and as to whether, if so cognizant and competent, he was able to resist the criminal impulse. Such an expert inquiry should be provided for the accused, whatever their circumstances, as a judicial provision to ensure a fair and just trial.

2. The appointment of a mixed commission of judges, counsel, solicitors, and medical experts for the consideration of the question of dealing with inebriates who have been convicted of a criminal offence. This inquiry should have special reference to the best procedure to be pursued; whether, 1, if penal, by cumulative punishment or otherwise; or, 2, if curative, by medical treatment for a diseased condition, with due provisions for classification, occupation, hygienic measures, and elevating influences."

ANOTHER DANGER IN THE PROFESSION.—CHARGED WITH KISSING.—An Irish physician was recently tried under the charge of attempting to kiss a young married woman while in his consulting room. Five thousand dollars represented the amount claimed for damages. The woman's story proved to be exceedingly incredible, and there was little doubt of its being the creation of an hysterical mind. The jury promptly found a verdict for the physician.

TREATMENT OF INFLUENZA.—Based upon his observations during the epidemic of one year ago, Dr. John William Moore, of Dublin, concludes as follows, touching treatment: "The treatment of the affection turns upon common-sense principles. It is expectant, palliative, and symptomatic. There is no specific for influenza; but the most useful drugs to employ in its treatment are, 1, quinine; 2, antipyrin (except in young children, and the weakly); 3, salicylate of sodium, especially in effervescence; 4, phenacetin; and 5, effervescing citrate of caffeine."

MEDICAL ITEMS.

MISSOURI MEDICAL ASSOCIATION.—The date of meeting of this Association is given as May 19, 20 and 21—instead of May 12, as formerly announced—and the place of meeting is to be Excelsior Springs.

ETHER DRINKING IN MICHIGAN.—A correspondent communicates to *The Medical Age* the prevalence of one sort of ether drinking—the compound spirits of ether—in the northern counties of the State of Michigan, principally among the Finns, Swedes, and Poles. It is generally consumed with alcohol or whisky.

A RARE CASE.—Dr. Thomas D. Dunn of Westchester, Pa., reports (*University Medical Magazine*, May, 1891) a case of ligation of the common carotid artery, in a child three and one-half years of age, for hæmorrhage following peritonsillar abscess, and with the result of recovery of the patient. The case is remarkable, both from the disease, and the operation in one so young.

THE CHAIR OF THERAPEUTICS IN JEFFERSON MEDICAL COLLEGE.—Dr. Hobart Armory Hare was elected, April 22, 1891, by the Trustees of Jefferson Medical College, to fill the Chair of Materia Medica and Therapeutics. Dr. Hare is a young man, yet has already distinguished himself as an investigator and medical author, and will no doubt find scope for continued and added renown in the field of his new relationship.

STIMULUS FOR MEDICAL WORKERS.—Dr. Bailarger, the late eminent French alienist, has bequeathed to the French Academy of Medicine a sum sufficient to produce a biennial revenue of \$400.00, which will be offered as a prize for the best work appearing—during the intervals between which it becomes available—on the subject of mental diseases.

A RESIGNATION.—It is announced that Prof. J. M. DaCosta has resigned the Chair of Practice of Medicine at Jefferson Medical College which he has occupied with such honor for upwards of nineteen years.

CASES IN OBSTETRICS.—An interesting tabulation of the first 1,000 cases of obstetrics in the Sloan Maternity Hospital, New York City, appears in the pages of the last issue of the *American Journal of Obstetrics*. The oldest patient con-

finied was 46, while the youngest was 12 years and 10 months of age. The largest number (659) were between 20 and 30 years old. Also in the largest number (547) it was the first pregnancy, while in one case occurring in the table it was the patient's seventeenth confinement. Of the presentations 935 were vertex, and of these 610 occupied the L. O. A. position. As to operative interference, there were 112 in which it was required, as follows: induction of labor, 12; forceps, 83; version, 14; craniotomy, 3. Of twin cases there were 13, about one in seventy-seven of the whole number of women delivered. In the forceps cases the returns are certainly noteworthy. Out of the 83 cases none of the mothers died. Of the 84 children 75 were living, 9 still-born, including premature twins. In nearly all the cases the long curved forceps (McLane's) were used, both in high and low operations. Of the fatal cases in this report we have as causes chronic Bright's disease, 1; rupture of uterus, 1; placenta prævia, 1; placenta prævia with contracted pelvis, 1; eclampsia, 1; septicæmia, 1; total, 6. On analyzing these deaths it is seen that one was from chronic organic disease and not labor; in another the patient was moribund when taken from the ambulance; in a third—placenta prævia—there was much delay and great bleeding before assistance could be given. The septicæmia case was admitted while in the second stage of labor, and was in a very filthy condition. The showing, therefore, is highly creditable.

ETHER DRINKING IN IRELAND.—The statement lately put forth of the prevalence of ether drinking among certain classes in Ireland, has had confirmation before a British committee. The Rev. Dr. Carter, Rector of Cookstown, gave evidence that ether drinking was not a rarity, but quite a common practice. Children, even, were given to the habit, obtaining the intoxicant from beggar-women who tramped the country. On market days particularly a great number of people would keep themselves drunk at small expense, taking a given quantity of ether at certain intervals. Some Government action will probably be taken at an early date.

FUND FOR A BIOLOGICAL LABORATORY.—The trustees of Columbia College have determined to devote the late Mr. Charles M. DaCosta's bequest of \$100,000 towards a laboratory of biology.

TOPICS OF THE WEEK.

THE CENTENARY OF THE MICROSCOPE.

It is generally thought that the invention of the microscope goes back to the close of the fifteenth century, or, to be more precise, to the year 1590, when, in the city of Middleburg, in Holland, two spectacle-makers, named Janssen, invented both the telescope and the microscope. This date for the invention, according to which its third centenary would arrive in 1890, does not rest on authentic documents, but is based on assertions published in 1665 by the physician, Peter Borel. He denied that Galileo, Drebbel and others deserved the credit of having invented the telescope; and in order to demonstrate that the invention of that instrument, as well as of the microscope, was due to the Janssens, produced some documents which showed that the two spectacle-makers, having invented the telescope in 1590, presented a specimen of it to Prince Maurice, Stadtholder of the Netherlands, and to the Archduke Albert. Later on, however, the telescope of Prince Maurice became a microscope, in a letter of William Borelli, who declared that he had always heard in Middleburg, his native city, that the Janssens had invented these optical instruments, and further that, when he was ambassador at London, in 1619, he had seen in the hands of Drebbel the identical microscope that the Janssens had presented to Prince Maurice.

Professor Govi, however, in a work which demonstrates the excellence of his judgment and his vast erudition, has collected a series of documents, which not only seem to restore the merit of the invention of the microscope to Galileo, but show the various vicissitudes of the discovery itself. The first hint of the transformation of the Holland telescope into a microscope is found in a little book published in 1610 by Wodderborn, a pupil of Galileo. Speaking of the wonderful qualities of the telescope, Wodderborn adds, in praise of Galileo, that "with the instrument could be perfectly distinguished the organs of motion and sensibility in the smallest animalcule," so that the particular formation of multiplied eyes in very small animals could be perceived. This new application of the telescope by himself Galileo did not deny, though he never directly affirmed it. In the National Library at Paris is preserved a letter by Canon Tarde, in which he speaks of visiting Galileo in Florence, in 1614, when the latter was sick in bed. Notwithstanding, to Tarde Galileo gave ample explanation of a microscope then in his possession.

Whether the invention of the simple microscope be due to Janssen or Galileo, to Drebbel is due the merit of having produced at Rome, in 1624, the compound microscope. The difference between the two hardly needs explanation. The simple microscope magnifies with a single lens, or with several lenses so close together that they act like a single lens. The compound microscope has two or more lenses, separated by a convenient distance from each other, and which act separately. In 1669, Eustachio Divini constructed a colossal microscope which magnified 140 times. A little after, Bonannus invented a horizontal microscope which magnified 300 times.

In the seventeenth century were laid the foundation of micrography, a science which, by the study of the minute anatomical elements and their functions, has made such great progress under the name of histology, and been such a fertile cause of important discoveries. With the microscope, Malpighi, by the minute examination of the tissues, confirmed the theories about them he had previously formed; Lenwenhoek discovered the globules of the blood and the structure of the nervous fibres; and Swammerdam dissected insects, of the most minute organs of which he gave descriptions still considered perfect.

In the eighteenth century, observes Henoque, but few modifications were made in the microscope. To mention all the improvements made in the instrument during our century would be tedious. During the last forty years enormous advances have been made in science by the aid of the microscope, of which the usefulness has been greatly increased by the skill with which the matter to be examined is prepared, and by the aid of photography. Micro-photography dates from 1810 only; but since that date it has had an uninterrupted series of noteworthy improvements.

Besides histology, created by the microscope, by which our acquaintance with the most hidden structure of organisms is constantly increasing, bacteriology, with its rapid succession of discoveries of the highest importance, owes its existence to the microscope. Those little beings, those microorganisms, which, by the change of the medium in which their evolution is effected, can produce so much good or so much evil, and of which it takes several millions to occupy the tenth part of half an inch in space, can now be identified according to their species, notwithstanding their changeable aspect. We can estimate the rapidity of multiplication, the number, the dimensions, and the singular manner in which by dividing themselves, or by means of a sort of buds or spores, the microorganisms reproduce themselves.

In the examination of the inorganic world the microscope has had results not less precious. The wonderful phenomena of crystallization, the exact form of the crystals, the more precise in proportion to their minuteness, the modifying properties of the light called forth by the thinnest layer of a mineral, the interior texture of rocks, all these can be studied with a precision impossible before the invention of the improved microscope. And, finally, not to mention all the triumphs achieved by the instrument, it has had an application which formerly would have seemed paradoxical, since the microscope has been employed to show the particulars of the nature of the surface of the planets, particulars which have been made clear by microscopic observations of instantaneous photographs.—Ernesto Mancini, *Nuova Antologia, Literary Digest*.

MEASURING THE PERCEPTION OF ODOR.

At a recent meeting of the French Academy, Secretary Berthelot exhibited a new instrument called the "olfactomètre." The inventor is M. Charles Henry. The object of the apparatus is to determine the minimum rate

of odoriferous vapor per cubic centimetre of atmospheric air perceptible to the human olfactory nerves. The olfactometer consists principally of a graduated glass tube which moves within a paper envelope. The tube is held to the nose and the paper gradually withdrawn. As soon as the subject of the experiment perceives the odor of the material contained within the glass tube, the latter is withdrawn, and the quantity of vapor which has escaped is calculated from the known capacity of the tube, and the degree marked by the paper envelope. The cubic space affected by the odorous vapor is simultaneously determined by means of a small areometer. The inventor of the instrument shows that the perceptibility of different odors by different subjects varied enormously, the two limits of his experiments falling between 2 milligrams of ether per cubic centimetre, and one-thousandth of a milligram of oil of wintergreen per cubic centimetre.

FRIEDLANDER'S PNEUMOCOCCUS AS A FERMENT.

It has been known for some time that Friedländer's pneumococcus is capable of inducing fermentative changes in suitable solutions of glucose and cane sugar, this having been first discovered by Brieger. His observations have quite recently been confirmed by Dr. Percy Frankland, Mr. Arthur Stanley, and Mr. William Frew, who have just communicated a paper on the subject to the Chemical Society of London. They further found that the organism ferments maltose, milk sugar, raffinose, dextrin, and mannitol, but that, like the bacillus ethaceticus, it does not attack dulcitol. They made a special study of the fermentations of glucose and mannitol, determining quantitatively the proportions in which the several products are formed. These products are in each case ethyl alcohol, acetic acid—generally accompanied by a little formic acid and a trace of succinic acid—carbon dioxide, and hydrogen. Both the glucose and mannitol were in all cases only partially fermented, and the decomposition of the glucose was especially incomplete, glucose being apparently less readily attacked by the organism than mannitol and cane sugar. The fermentation was not rendered more complete by furnishing the organism with a more abundant supply of nitrogenous food. The products of the mannitol fermentations were not only qualitatively similar to those obtained in the fermentation of the same substance by the bacillus ethaceticus, but the relative proportions in which they were formed were almost identical, the ratio corresponding closely to the molecular proportions $2\text{C}_6\text{H}_{12}\text{O}_6 : \text{CH}_3\text{COOH}$.—*The Lancet*.

THE POPULATION QUESTION IN FRANCE.

This subject naturally continues to exercise the minds of French statisticians and scientists. Dr. Jomille discusses it in the February number of the *Archives de Zoologie*. The true cause of the stationary population appears undiscovered—perhaps the theory that the race is naturally not prolific, or that climate and habits are against fertility is correct. Levasseur, Dr. Jomille notes, has recently shown that the question of professions and of non-religious ideas has little direct influence on fertility.

Thus statistics make members of the liberal professions less prolific than farmers and business men, but the liberal professions best allow celibacy, or often enforce it, and late marriages are common. Social and religious ideas seem to have little influence, contrary to what might have been supposed. In strictly religious communities—Protestant as well as Catholic—a large family is held to be an honor, if not a blessing, and checks to impregnation are deprecated. Yet statistics show that the fertility of such communities is not higher than that of large bodies of men and women, chiefly laborers, where the religious element is weak and where checks are openly tolerated. Brittany, the Maritime Alps, and Corsica are fertile in children, and the population are strict in religious observances and almost free from corrupting influences; yet the inhabitants of the valley of the Garonne, also a strict and pious folk taken as a whole, have very few children. Lastly, some districts where the peasants are comfortably off, have a low fertility, others show an increasing population, whilst the same irregularity is seen in different departments, where the country people are poor and ill-fed.—*British Medical Journal*.

THE INFLUENCE OF EXERCISE ON DIGESTION.

Dr. Streng, in a lecture before the Medical Society of Giessen on the Influence of Exercise on the Digestion, which has been published in the *Deutsche Medicinische Wochenschrift*, states that he concludes from his own experiments that this influence is of a retarding nature. His experiments, however, suffer from the fact that he always injected 300 cubic centimetres of water before obtaining the contents of the stomach, so that the proportion between gastric juice and water continually varied. The first experiments in the clinic at Giessen were made on two dogs. Twenty-five grams of meat, suspended in 300 cubic centimetres of warm water, were twice injected into the fasting stomach, and after one feeding the dogs were compelled to remain for three hours in absolute bodily rest, while after the other feeding they were made to take active exercise. After the three hours the contents of the stomach were obtained and analyzed. The quantity did not essentially differ in the two cases; the experiments consequently tended to prove that exercise does not influence the time required for digestion. The chemical analysis is also detected no difference. The same results were obtained by substituting the white of an egg for the meat. The experiments were then repeated twenty-five times on three men with healthy stomachs. Two of these suffered from syphilis, and the third from incipient muscular atrophy. They were fed each time with 200 grams of minced meat, a bun, a plate of bouillon, and three spoonfuls of mashed potatoes, and the contents of their stomachs were obtained four hours and a half afterwards. The exercise after meals consisted partly in gymnastics, partly in walking; absolute rest was obtained in bed. These experiments gave the same results as those on the dogs, the difference resulting from the chemical analysis being especially imperceptible. The author therefore concludes that the gastric function is in no way influenced either by muscular action or by absolute rest.—*The Lancet*.

PRACTICAL NOTES.

INFANTILE DIARRHŒA.

1. Withdraw all milk for from twenty-four to thirty-six hours. 2. Regulate the quantity and quality of the food and the frequency of giving it. 3. Give plenty of cool water. 4. Reduce the temperature with the bath. 5. Give medicines of an antiseptic and astringent character and stimulants as needed. 6. Wash out the colon two or three times a day. — *Archives of Pediatrics*.

IODOFORM AND ARISTOL.

Dr. Richtmann recommends (*Nouveaux Rem.*) that aristol be used to replace iodoform, since it presents all the advantages of iodine and thymol without any of their disadvantages. Aristol does not cause irritation; its absorption is not followed by any phenomena of intoxication, and its odor is not disagreeable. Being less volatile than thymol, its use is especially indicated in extensive burns. It may be prescribed as a powder, or an ointment, or given in solution. The preparations used by Richtmann are as follows:

- R. Aristol pure, gm. 10.
- S. For external use.
- R. Aristol, gm. 1.
- Ether, gm. 10.
- S. For external use.
- R. Aristol.
- Ol ricini $\bar{a}\bar{a}$, gm. 1.
- Collodion, gm. 8.
- S. As a paint for the region affected.
- R. Aristol, gm. 2.
- Paraffin ointment, gm. 18.
- S. For local application.
- R. Aristol, 1 to 5 cgm.
- Cocoa butter, q. s.
- S. For urethral or vaginal bougies.

— *Medical Standard*.

SEDATIVE FOR BABIES.

Dr. Van Goidtsnoven, of Atlanta, gives a formula with which he has had most gratifying results in restlessness, spasms, deliria, and in all cases requiring a sedative, anodyne, anti-spasmodic or somnifacient.

- R. Camphor. monobromat., gr. xvi.
- Ext. hyoscyami fl., gtt. xvi-xxx.
- Syrup lactucarii (Aubergier's) f \bar{z} viij. \bar{m} .
- S. A tablespoonful every hour till relieved.

— *Divine Doctor*.

PHENACETIN IN SCIATICA.

Sciatica is not only one of those affections which are extremely annoying and painful to the patient, but on account of its persistency often greatly tries the patience of the physician. At the clinic of Prof. Landon Carter Gray most benefit has perhaps been obtained from phenacetin, given, say, in tablets of four to eight grains every three or four hours. There are a good

many cases, however, which do not respond to it very markedly. Doubtless, too, there are many cases of sciatica neuritis, rheumatism, gout, etc., in which a diagnosis of sciatica is erroneously made; but perhaps more frequently sciatica is mistaken for one of these affections. — *Practice*.

BISMUTH FOR ECZEMA OF INFANTS.

The following formulae are given in *Nouveaux Remèdes*:

- R. Bismuth, subnit., 5v.
- Zinci oxid. 5jss.
- Acidi carbolic. m. x.
- Vaseline, 5j. \bar{m} .
- To make an ointment.

In case there is much irritation paint on the following with a soft brush:

- R. Bismuth, subnit., gr. xl.
- Glycerine, 5jss.
- Acidi carbolic. gtt. xj.
- Aque roseæ, 5iv. \bar{m} .
- To be well shaken.

RESORCIN IN ACNE.

Isaak recommends the following:

- R. Resorcin, 5j to ijss.
- Zinci oxid. pulv., $\bar{a}\bar{a}$ 5jss.
- Amyli pulv., $\bar{a}\bar{a}$ 5jss.
- Liquid vaseline, 5v. \bar{m} .

Rub on the part affected morning and night, or it may be used at night only, and removed in the morning with sweet oil.

ACUTE BRONCHITIS.

The citrate of potassium is a favorite remedy of Dr. H. C. Wood in acute bronchitis; his formula is, he says, the most reliable and efficient sedative cough mixture that he has ever used:

- R. Potass. citrat., 5j.
- Suc. limonis, f5vj.
- Syr. ipecac, f5ss.
- Syr. q. s. ad, f5vj. \bar{m} .

Sig. A tablespoonful four to six times a day.

Another favorite expectorant with this writer is oil of eucalyptus, which may be given in five minim capsules every three hours. It is only of use after expectoration is established.

MOUTH WASH.

David uses the following mixture as a tonic and antiseptic mouth wash (*Medical News*, February 21, 1891):

- R. Thymol, 7 grs.
- Borax, 15 grs.
- Water, 1 $\frac{1}{2}$ ozs. \bar{m} .

A few drops of this are to be placed in a wine-glassful of warm water, and the mouth rinsed with it. In cases in which the breath is fetid, owing to deposits about the tonsils and gums, the following wash is said to be serviceable:

- R. Borate of sodium, 15 grs.
- Alcohol, 12 drachm.
- Water, 1 pint.
- Thymol, 7 grs. \bar{m} .

SOCIETY PROCEEDINGS.

Gynecological Society of Boston.

Annual (218th Regular) Meeting.

The Gynecological Society of Boston held its 218th regular meeting at the Medical Library on January 8, 1891, with the PRESIDENT, W. SYMINGTON BROWN, M.D., in the chair.

THE ANNUAL ADDRESS ON GYNECOLOGICAL PROGRESS

was delivered by the President, who said: Our third by-law requires that the retiring President shall deliver an Address upon the previous year's progress in gynecology,—a law, by the way, which, since my connection with the Society, has been rarely attended to. On the present occasion I propose to discuss very briefly a few recent suggestions by prominent gynecologists, principally relating to menstruation.

Dr. E. C. Gehrung, of St. Louis, read a paper before the American Gynecological Society at its meeting in Boston, in September, 1889, on arrest of menstruation. He thinks that sanguineous menstruation is an abnormal process, an inherited disease, eventually to be got rid of through the Darwinian process of evolution. He says that "menstruation is not necessarily sanguineous." The practical part of the paper consists in a proposal to arrest menstruation in all cases where the loss of blood would be injurious to the patient. He asserts "that bloody menstruation, whether profuse or scanty, may be safely repressed (preferably by the vaginal tampon) whenever the individual cannot or should not spare the blood thus wasted, and that great benefits may be derived from this restriction in otherwise incurable or partly curable cases." Dr. Gehrung has practiced this method successfully for several years. The vagina is thoroughly tamponed, a new tampon being inserted every 48 or 60 hours. Another member said that he also had employed this method with great success.

Dr. Johnstone, of Danville, Ky., strenuously objected both to the theory and to the treatment. He believes that menstruation results from the erect posture, as proved by the fact that menstruation occurs in the higher apes, who stand erect, or nearly so, most of the time. Quadrupeds possess a rich plexus of lymph vessels connected with the womb; whereas the human uterus is almost destitute of such vessels. The proposed treatment did not seem to meet with much favor by those present at the meeting.

Dr. A. W. Parsons, of Northampton, Mass., proposes to do away with napkins during menstruation and substitute an antiseptic tampon, inserted through a glass speculum, as soon as the premonitory symptoms appear. This is removed when saturated and another roll inserted. Dr.

P. claims that the tampon supports the congested uterus and is more cleanly. I have not learned that this suggestion has been generally adopted by women and scarcely expect that it will be practiced. One serious objection is that it necessarily keeps the vaginal walls apart, which naturally are in contact; and, judging from my own experience, it is a very difficult thing to induce patients to insert a cotton or wool tampon, even when it is needed to counteract prolapsus. They prefer to wear a pessary, which does not need to be removed for weeks or months. If used as a substitute for napkins, the tampon should consist of wool, with a covering of cotton, and a string attached to facilitate removal.

Dr. H. P. C. Wilson, of Baltimore, recommends the performance of laparotomy during menstruation. He refers to the paper of our Dr. H. R. Storer, read at the first meeting of the American Gynecological Society in 1876,¹ in which Dr. S. concludes "that for pelvic operations, all things being equal, it is better to select the week immediately following the cessation of the catamenia for all such operations." Dr. Wilson differs from this conclusion. He says, "for laparotomies involving the pelvic organs, my experience teaches me to select the uterine flood rather than the uterine ebb." This is the opinion of a surgeon who has had abundant opportunities to test it, and who is well known for conservative tendencies; and I think that the majority of gynecologists are now of the same opinion.

The question so frequently discussed during the last ten years, whether menstruation depends on ovulation or is independent of that process, has had some light thrown on it by a case recently reported in the *British Medical Journal* (Sept. 27, 1890). Dr. J. A. Robertson reports the case. The woman was 23 years of age. She commenced to menstruate before she was 14 years old, and continued to do so regularly for six years. During the following three years the quantity became less and less and the periods irregular, until Sept., 1887, when the flow stopped entirely. Pain, from the ovaries, extending to the top of the sacrum, kept constantly increasing; lately she spat up blood every day. Both ovaries were removed on Jan. 29, 1889, and the patient made a good recovery. She began to menstruate the following April, and continued to do so regularly until October. In June she was married, and was delivered of a boy August 13, 1890, which weighed about 10 pounds. The labor was protracted, forceps were used, and the child was still-born.

I think it is evident that a portion of one ovary must have been left, or supplementary ovarian tissue existed; and the fact that impregnation resulted weakens the Tait argument that menstruation is independent of ovulation. Dr. R. says:

¹Dr. Storer's paper does not appear in the *Society Transactions*. It was afterwards published in the *Edinburgh Med. Journal*.

"I was not aware of leaving any ovarian tissue. Indeed, my aim was to extirpate the ovaries thoroughly, and I thought I had done so. I suspect, however, that a small portion of healthy ovarian tissue had reached up to or beyond the hilus of the right ovary, and that this may have taken on regular ovarian functions. This, of course, is merely conjecture."

Dr. L. C. Coe has an excellent paper in the *Medical Record* for August 9, 1890, on "The Dangers attendant upon Artificial Prolapsus Uteri." These are: overstretching of the ligaments; tearing of adhesions; starting inflammations; and causing an abscess to burst internally. I have no doubt that the rude way in which the uterus is often brought down to the vulvar orifice occasionally causes one or more of these mishaps. We are too much disposed to copy the doings of German hospital surgeons, who operate on a class of women widely different in constitution from the bulk of our American women. And while I do not say that artificial prolapsus should never be produced, I think that the seldomer it is had recourse to the better it will be for our patients.

The uterus normally is the most movable organ in the body. Practitioners sometimes forget this fact, and try to fix an organ by a pessary or otherwise, which nature intended should be allowed a great deal of freedom. And the practice of gynecology seems to change its position about as freely as the uterus itself does. No specialty I am acquainted with is so much subject to fashionable changes as ours is, keeping pace with the multimod revolutions which fashionable clothing inaugurates. But I need not waste your time by proving an assertion which I scarcely expect will be disputed.

Before closing allow me to call your attention to a few personal items. I believe that a greater inclination to look after constitutional measures than formerly has arisen in the profession. Dr. Field and the late Dr. Warner did more than the rest of us to bring about this result. I hope to see some of the younger members follow in their footsteps; for the constitutional field is not yet thoroughly gleaned.

Some progress has also been made in recording the after effects of surgical operations. Sir Spencer Wells inaugurated this reform, and has spent more time in perfecting it than any other surgeon. One of the most recent discoveries in this field is that a mild melancholia, generally of brief duration, is apt to follow surgical operation on the genital organs. I have seen one case recently, and several others have been reported to me.

So far as I am aware there has been only one death of an active member during the past year. Several members have resigned, but at least an equal number have joined our Society in 1890. I am pleased to see that a considerable number of the new members are young men, full of en-

ergy, believers in the virtue of cleanliness, some of whom will probably leave names behind them which the medical world will "not willingly let die."

If I might be allowed to give a hint to men much better qualified than myself, it would be this: Cultivate an *esprit du corps*. We are members of the oldest Gynecological Society in the world—not in itself a slight honor. Let us make up our minds to stand by one another, to take an interest in one another's success in consultation and otherwise; subject, of course, to the welfare of the patient, which is the first dogma in every good surgeon's creed. And I have no doubt, when the time comes for each of us to render an account of our stewardship, he or she will not be embarrassed by the reflection that "it is more blessed to give than to receive."

Tennessee State Medical Society.

Fifty-Eighth Annual Meeting held in Nashville, April 14, 15, and 16, 1891.

(Concluded from page 644.)

SECOND DAY—AFTERNOON SESSION.

DR. A. J. SWANEY, of Gallatin, contributed a paper on

RETAINED PLACENTA IN MISCARRIAGE; HOW SHALL WE TREAT SUCH CASES?

He said the dangers from retained placenta in miscarriage were hæmorrhage and septicæmia. When the delivery of the placenta is prolonged ought we still to abstain; ought we to wait or ought we to interfere actively in order to forestall these dangers which almost certainly will result and further interfere at a time when it is far easier than later to remove the placenta? Those who favor active interference are Tyler Smith, Murray, Simpson, Leishman, Mundé, Grandin, and many others. The reasons given for active interference are the frequency of these dangers in prolonged delivery of the placenta. Simpson directs that if the cervix is dilated or patent to act at once; if it is not dilated he dilates it at once. The woman is then anesthetized, the uterus depressed as much as possible by the external hand and with the index finger of the other hand he removes the placenta and membrane. If he cannot sufficiently depress the uterus with the hand he does not hesitate to forcibly drag it down by a double tenaculum fixed in the cervix. Mundé and Grandin go still further and curette the cavity of the uterus with special instruments made for the loosening of adherent placenta and its removal from the uterus.

The authorities who counsel waiting for serious complications before interfering are just as many. We mention Ramsbotham, Davis, Burns,

Fleetwood Churchill, Grailey Hewitt, and many others. Active intervention does not mean unnecessary interference. Nature is ever to be given a chance, but when we see that her efforts are futile certainly it is but rational to assist her, and this should be done as directed by Mundé, by placing the woman in the left lateral position and with a dull wire curette remove the placenta or any part of the secundines that may remain through a Sims speculum. This is far better and easier than the method advised by Simpson, of dragging or pressing down the uterus and introducing the finger into the uterine cavity. The uterine cavity should then be washed out with hot water, slightly carbolyzed, through a Jameson's uterine douche, and this should be repeated every six or eight hours until all fetor disappears from the lochial discharge.

Hæmorrhage after miscarriage, even when we believe the placenta and secundines have been removed, invariably means retention of a part of the placenta or secundines, said the speaker. Profuse hæmorrhage may occur for weeks from this cause, and in such cases we should boldly explore the uterine cavity and remove any offending matter that may be present. In the first twelve weeks of pregnancy the dangers from hæmorrhage and septicæmia are not so great and the expectant plan is more justifiable. After the third month it is criminal negligence to wait and subject a woman to the dangers arising from retained placenta when she can be relieved by an operation, which, if properly done, can do no harm, and spare her the risk of hæmorrhage and septic poisoning. In short, the author believes the early removal of the secundines is easy and safe, and forthwith guarantees the woman against the dangers of hæmorrhage and sepsis.

DR. J. L. JONES, of Bells, read a paper entitled

INDIGO AS AN EMMENAGOGUE,

in which he said his attention was first directed to this drug as an emmenagogue in July, 1887, from an essay published in the *Medical and Surgical Reporter*, of Philadelphia, by Dr. S. L. Gount, of Lafayette, Ind. Acting on the suggestions offered by Dr. Gount, he had used it in many and various cases.

His first case was a young lady, 20 years of age, who had not menstruated in five months. He had been treating her for three months with the usual remedies without any effect, so he made up his mind to give indigo a trial, which he did. He ordered indigo ʒij, subnitrate of bismuth ʒss, well mixed. Of this the patient took one-half teaspoonful in one-third of a glass of water, three times daily, for nearly four weeks, when one day he was sent for in great haste. On his arrival he found the patient in bed, and comfortable. He was then told by the mother that her daughter, while walking in the garden, without pain or

warning of any kind, began to flow. The gush was followed by a gentle flow which lasted only for a short time. In five days she was well, and has not suffered from amenorrhœa since. Dr. Jones has since used indigo in thirteen cases with but one failure, and this case proved to be pregnant.

During the administration of the drug the os uteri becomes soft and patulous, admitting the end of the index finger. There is often a serous discharge from the vagina. The urine becomes brownish green in color, and its odor is offensive. The stools are watery and offensive.

THIRD DAY—MORNING SESSION.

DR. J. A. WITHERSPOON, of Columbia, read a paper on

DIABETES,

in which he confined his remarks principally to diabetes mellitus. He said the term diabetes mellitus is a symptomatic one, being a deviation from health in which the processes of nutrition are seriously deranged, and presenting a group of complex symptoms, the most conspicuous of which are, first, frequent micturition, passing large amounts of pale, saccharine urine. Coincident with this is an insatiable thirst and dryness of the mouth and fauces, which is by far the most annoying symptom, the freest draughts of water giving but little or no satisfaction. The skin becomes dry and harsh, with complete absence of perspiration, and followed by a general pruritus, sometimes impossible to relieve. These were some of the many symptoms of the disease.

The etiology of the disease is yet an unsolved problem. It is an affection of adult life, but few cases being reported in children, and those always fatal. The only recovery reported, so far as the speaker was aware, was a girl 12 years of age.

The treatment is conveniently divided into dietetic, medicinal, and the hygienic. The dietetic is by far the most important. We must exclude from the bill of fare all food stuffs containing starch or sugar, for two reasons: 1. The normal action of the liver in its glycogenic function is seriously deranged and incapable of oxidizing the maltose sent to it by the digestion of carbo-hydrates, and they are therefore useless aliments. 2. They seem to aggravate and increase the glycosuria. A strict meat and green vegetable diet agrees better than any other. Some give milk, others forbid it entirely. He had found in the few cases he had treated that it was impossible to continue for long periods any one diet. The pure skim-milk diet is meeting with much favor. Alcohol, and all spirits, except small quantities of light wine or beer, must be forbidden. This regimen alone will lessen the quantity of sugar eliminated, but it is necessary to use in connection certain medical treatment. The drugs

giving the best satisfaction are opium, of its alkaloids, morphia or codeia; ergot, arsenic, and many others. Of all the drugs mentioned, codeia has been by far the most satisfactory in Dr. Witherspoon's hands. It was first suggested by Dr. Pavy, of London, and has the great advantage over its sister alkaloid, morphia, in not producing sleep. It is more efficient, less dangerous, and does not produce the troublesome constipation caused by morphia or opium. Next to it, the speaker would place ergot, for its physiological effect upon the blood-vessel walls. Recently sulphonal and antipyrin have been used with reported good results. He had never used antipyrin in this disease, for the reason that it is recommended in from 30 to 60 grain doses. He did try sulphonal in 10-grain doses, three times a day, and in two days it produced so much giddiness and sleepiness that he quit giving it. He had only used arsenic as an alterative tonic after the sugar had disappeared from the urine. With this treatment the patient should be advised to take light exercise, always short of fatigue, and their surroundings should be good and well ventilated. Alkaline carbonated waters are often of great utility.

TREATMENT OF STRICTURES OF THE MALE URETHRA.

This was the title of a paper read by DR. J. W. HANDLY, of Nashville.

He said strictures of large calibre, if they be recent, but poorly organized and of the linear variety, may be treated by dilatation, which must be continued for months. But should the stricture be densely fibrous, and not easily dilatable, the cutting operation becomes necessary, for which purpose he prefers the Otis improved dilating urethratome with which the surgeon can accurately divide any stricture to any size desired.

Strictures of small calibre, situated in advance of the bulbo-membranous junction, unless seen very early and found to be unusually soft and dilatable, furnish a typical condition for internal urethrotomy, that in which it is attended with the least possible danger and greatest prospect for a permanent cure. Should the contractions be so great that the Otis urethratome cannot be used, he had found Bank's whalebone dilators, which are made in four sizes, of great advantage in opening the canal so as to admit of the urethratome, and considered them very useful.

Strictures of small calibre posterior to the bulbo-membranous junction require a very different course of treatment, since internal urethrotomy at this point is often attended with profuse hæmorrhages, fever, rigors, or other disturbances equally as disagreeable. Strictures of this variety permeable only to filiform bougies, may be treated in one of the four following ways:

1. After the filiform has been introduced it

may be allowed to remain *in situ* for two or three days and another passed alongside of it to serve as a guide for the introduction of a tunnelled sound, later to be followed by the ordinary soft or steel bougies. This is good and safe surgery in the absence of retention.

2. The surgeon may attempt to conduct a tunnelled sound over it at once, to be followed by gradual dilatation.

3. He may conduct over it a grooved staff and then proceed to the performance of external urethrotomy, or,

4. He may use the staff as a guide for the Massionneuve urethratome and may immediately perform internal urethrotomy.

OFFICERS FOR 1892.

The following officers were elected for the ensuing year:

President—Dr. J. W. Penn, Humboldt.

Vice-President for Middle Tennessee—Dr. J. A. Witherspoon, Columbia.

Vice-President for East Tennessee—Dr. C. E. Ristine, Knoxville.

Vice-President for West Tennessee—Dr. C. H. Lovelace, Dukedom.

Secretary—Dr. D. E. Nelson, Chattanooga.

Treasurer—Dr. J. P. C. Walker, Dyersburgh.

Next place of meeting, Knoxville, second Tuesday in April, 1892.

DOMESTIC CORRESPONDENCE.

Forced Respiration.

To the Editor:—In a recent number of THE JOURNAL I find an address by Dr. G. E. Fell, on "Forced Respiration." Allow me to draw your attention to an article which appeared in the year 1822, and which may possibly be of interest to the medical fraternity.

I am in possession of the *London Journal of Arts and Sciences*, Vol. 3, London, 1822, page 93: "Account of an apparatus for restoring the lost action of the lungs, in consequence of suspended animation from drowning, etc.; invented and communicated by John Murray, Esq."

There is, perhaps, no subject which ought to excite a deeper interest, than that of suspended animation. The number of human beings who are hurried suddenly out of existence, by being deprived of that necessary pabulum, atmospheric air, form annually a lamentable catalogue; and, although a Goodwin, a Hawes, a Cogan, and many others of the benevolent of our species, have done much in exciting attention to this interesting subject, yet it is to be lamented, that the scientific world has not paid so much attention to it, as its importance most unquestionably and imperiously demands.

FORBES' SCINTILLA LATEAT.

Plate 4, figs. 3, 4, and 5, exhibits drawings of an apparatus, which I have invented for restoring the lost action of the lungs. It consists of two cylinders concentric with each other; the inner one is three inches in

diameter, the exterior one four inches, forming a space of half an inch round the cylinder, which is to be occupied with water, heated to 98 degrees, the animal temperature to elevate the air contained in the interior cylinder to that degree.

The piston is solid, and moves horizontally: the piston rod is perforated, to receive a metallic pin, which, being introduced, shortens the stroke, checked, by the plate covering the end of the cylinder, and gives the means of apportioning the volume of air to the capacity of the lungs, which is to be determined by the victim of experiment being of tender age, or adult. This will obviate the danger of rupturing the lungs. To the pipe proceeding from this cylinder, is affixed a cell and cock, with an elastic tube terminating in a mouth-piece and plate of leather.

The stopcock is so constructed, that, when the handle is parallel with the pipe, as in the figure, there is a free communication established between the lungs and the cylinder, to the exclusion of external air. When on the other hand the cock is turned the quadrant of a circle, the communication with the lungs is cut off, and there is a free channel opened between the cylinder and the external atmospheric air.

The lateral cell, appended to the cock, will be found of varied use and importance. Should the subject of experiment have been the victim of carbonic acid gas (choak damp), a drop or two of ammonia may be mingled with the air in the cylinder, and when thrown into the lungs will condense the mephitic gas. If a septic poison—as sulphuretted or arsenicated hydrogen—have occasioned the asphyxia, a few drops of solution of chlorine or nitromuriatic acid will destroy the septic virus. Should the atmosphere be too dry, a small portion of water put into the cell, will mix with the air, and impart additional elasticity: and if we desire an additional stimulus, a drop or two of ether posited here, will expand in the air of the cylinder, and this mixed atmosphere will act with all the consequence of nitrous oxide. These provisions for various reasons, are valuable auxiliaries in returning respiration.

When the machine is to be used, the victim of suspended animation is to be raised in a gently inclined position opposite to the operator; the nostrils are to be plugged up, and the plate of leather fixed on the mouth, as nearly air-tight, by means of white of egg, etc., as possible; this must be kept in its position by means of a ribbon tied round the head. The operator over against the victim, manages uniformly and equally the piston. The apparatus being adjusted in the manner described, the air is first withdrawn from the lungs, and then ejected laterally; and the piston rod being drawn to the extremity of the cylinder—if an adult—the pure atmospheric air fills the instrument; the communication with the lungs being restored by turning the stopcock parallel with the pipe, the operator begins. About twenty plunges of the piston a minute may be the proper number. It will not be necessary to change the included air until natural respiration is restored; because, until this does take place, the blood cannot eject its excess of carbon, the consequence of the circulation of that fluid; but when this is required, it is instantly accomplished in the manner already described.

This invention has met with the most unequivocal testimony of approbation from several eminent physicians and surgeons, and gentlemen of distinguished mechanical genius.

The apparatus, with my latest improvements on it, of which a drawing accompanies this paper, is formed of Britannia metal, and has been presented by me to the Royal Humane Society. It is made to rest in a groove, which may be easily fixed to a table by means of a clamp. It possesses an attached pin, which being fixed into the perforated piston rod, readily apportions the injected air to the capacity of the lungs, whether of an adult or child. Hence there can be no danger of injuring the lungs. The

flexible tube should be formed of caoutchouc, and be perfectly elastic and pliant like the bougies.

In this improved apparatus, the heated water—which will be better at some degrees above 98 to compensate for the loss of temperature sustained by the conducting of the metal and the transit of the air through the pipe into the receptacles of the lungs—is supplied exterior to the cylinders and above; thus affording every facility of ascertaining the temperature by a thermometer. There is also an exit pipe, with a stopcock to permit the water when cooled, to flow, so that without altering the position of the apparatus in the least, it may be supplied with heated water anew. The valve which communicates with the lungs, is Mr. Trevithick's conical one, used in the steam engine. The internal cylinder, being one foot long and three inches in diameter, will contain 8.32 cubic inches of air; about half this extent will be sufficient for an ordinary inspiration.

ADDRESSES.

UPON THE USE OF THE ELASTIC LIG-
ATURE IN THE SURGERY OF THE
INTESTINES.

The Chairman's Address, delivered before the Section of Surgery and Anatomy at the Forty-sixth Annual Meeting of the American Medical Association, held at Washington, D. C., May, 1891.

BY THEO. A. MCGRAW, M.D.,
OF DETROIT.

Gentlemen:—Under the regulations now in force in the American Medical Association, provision is made for two addresses on Surgery, one by a gentleman appointed for the purpose, before the general body of the Association, and the other for delivery before the Surgical Section by its chairman.

It was evidently the design of the Association in adopting this order of exercises, to have the morning address devoted to the general subject of Surgery—its history, its progress, its present condition and its relations to general medicine. The reason of the second address is not so obvious, but it is natural to suppose that, as provision has been made for a general address before the entire Association, it was meant that the one held before the Surgical Section should be more special and technical in character. Indeed, it would hardly seem proper or advisable to consume the time of this body of experienced and learned surgeons, in rehearsing what every one is familiar with, the changes which have taken place in our art during the past year, nor in discussing themes of general interest which have been worn threadbare in the countless meetings of this and other societies. For these reasons, I have on this occasion chosen, for the topic of my address, a subject that is limited in scope, technical in character, and of particular interest only to operating surgeons.

In common with many American surgeons, I have been intensely interested in the surgery of the intestines. It is well known to you all that the impulse which turned the attention of the profession in the United States in this direction was given by the now famous labors of Dr. Senn, the importance of which is to be measured, not alone by the value of the operative measures which he in-

troduced, but also and even more by their influence on the professional mind, not only in America, but all over the world. For his experiments in a field at that time very little cultivated, served to place procedures, which had previously been regarded as odd and experimental, on a sound pathological basis, and we began to perceive a real therapeutical value in operations which most surgeons had regarded as of doubtful propriety. The operation for intestinal anastomosis introduced by Wölfler and practiced to a limited extent by German surgeons, had not, in this country and England at least, become recognized by the profession, until Senn had simplified its methods and demonstrated its usefulness. Since the publication of his papers on that subject, great activity has been manifested by American surgeons both in operating and in improving the technique of the operation. In fact, I fear that some in the profession have become a little weary of the constant recurrence in our periodical literature of papers on modifications of Senn's operation for intestinal anastomosis. I shall nevertheless, at the risk of adding to this weariness, ask your attention to-day to a new operation, which I have devised for this purpose, and which I believe will prove of superlative value, in a limited class of cases. The reasons for endeavoring to modify the established operations will be apparent to every surgeon experienced in this kind of work. The operation for intestinal anastomosis is indicated: 1. Wherever there is a chronic stenosis of the gut, such as we find in cancer of the pylorus, or small or large intestine, or in cicatricial contraction from injury or ulceration, which cannot be otherwise radically cured. 2. Whenever there is acute obstruction that cannot be relieved by any other procedure, such as sometimes occurs in volvulus or in entanglement of the gut with Meckel's diverticulum, or in that kind of obstruction recently described by Prof. Kundrat, of Vienna, in which the duodenum is compressed by the mesentery of the small intestines; and 3. In some cases of gangrenous hernia, false anus and intestinal fistula.

In the vast majority of all these cases, the patient comes to the operation already exhausted, with a vitality so low that even a long continuance of the anæsthesia becomes a source of dan-

ger. For that reason the operation for intestinal anastomosis is one that demands all possible speed. It may be truly said that its danger is in direct proportion to the time occupied in its performance. The longer the patient is under the anæsthetic the greater the danger from vomiting and exhaustion. The longer the intestines are exposed to the air the greater the danger from shock and the greater the liability to bacterial infection. It becomes important, then, to devise plans of operation which will occupy the very least possible time. Whatever plan may be adopted the rapidity of its execution will depend, of course, largely upon the personal equation of the operator. I have experimented with various methods, and find that the time occupied in making an anastomosis after the intestines have been exposed and brought out on to the abdomen, by the old method of incising the intestines and uniting their cut edges by a double row of sutures, is from twenty-five to thirty minutes, and by Senn's method from fifteen to twenty-five minutes, according to the good fortune of the operator in keeping the many needles and threads from becoming entangled. I believe that these figures will represent pretty accurately the time consumed in the process by the average operator, if he have any experience whatever in this particular kind of work. Operators of exceptional skill might accomplish it in much less time, while those who had not previously qualified themselves by practicing on the lower animals would require a much more generous allowance of time. There can be no doubt that the reduction of this time by ten or fifteen minutes would in many cases make all the difference between life and death—success and failure.

Besides the dangers which result from the time consumed in the operation, there are others which are caused by the operation itself. One of these is the escape of the contents of the intestine into the abdominal cavity, either at the time of operation or afterwards from defects in healing. How serious this danger is the history of operations on the intestines will show. This source of danger is common to all those methods of operating in which the junction of the intestines is preceded by incision into their cavities. Still another danger is that of hæmorrhage from the cut walls of the gut. While this danger is not great if the operator cut in the middle line of the convex border of the intestines, as far away as possible from the mesentery, yet there are cases of unusual vascularity in which the bleeding may be serious, not so much from the difficulty of its control as from the expenditure of time required in accomplishing it. To perfect this operation, then, we must devise some means by which the difficulties and dangers of our present methods may be lessened or avoided.

On considering the matter it seemed to me that

if some method could be invented by which the junction of the intestines could be effected before the formation of the opening of communication between the two coils, two of the especial dangers, viz.: that of hæmorrhage and that of fecal extravasation, might be altogether eliminated, and that possibly the duration of the operation might also be much lessened. My first thought was of a metal clamp with two thin arms connected with a hinge and furnished with a strong spring. The two arms were to be thrust through the opposing intestines and then brought sharply together with the spring. In this way I thought a force could be brought to bear upon the intestinal wall which would gradually cut its way through, while adhesive inflammation was binding the outer surfaces together. I believe, still, that this could be done to advantage, but some practical difficulties in procuring the desired instrument, led me to abandon it temporarily for another and more simple contrivance, which thus far has acted admirably in my hands, and that is the elastic ligature—and this is the theme of my paper to-day, "The use of the elastic ligature in the surgery of the intestines." The value of the elastic ligature in cutting through inclosed tissues has long been known to the profession in connection with the treatment of fistula in ano, of piles, and small polypoid tumors of the rectum and skin. In 1884 Dr. J. McF. Gaston, of Atlanta, Ga., used it and other forms of ligatures in experiments on dogs which had for their purpose the establishment of a fistulous opening between the gall bladder and duodenum. Later still Lücke had used it successfully for the removal of a pedunculated cancer of the liver.

I learned very recently from Professor Dr. Helfenrich, of Greifswald, that some experiments had been made by Dr. Franz Bardenheuer, at present an assistant in Professor von Bergmann's clinic in Berlin, which had for their object the production of intestinal anastomosis by the use of an elastic ligature, and through his great kindness have been enabled to secure a copy of Dr. Bardenheuer's paper from the author himself. The paper is entitled "Experimentelle Beiträge für Abdominal Chirurgie," J. Dietz and Baumsche Druckerei, 1888, and states the results of many experiments similar to my own. His method, however, was materially different from mine, and consisted in connecting the intestines together by three or four rubber ligatures, which were joined together in loops like a chain, each loop containing about 1½ centimetre of tissue. He, also, evidently ignorant of Dr. Gaston's previous experiments, operated once successfully on a dog by the same method, for the production of an anastomosis between the gall bladder and duodenum. These experiments of Dr. Bardenheuer do not seem, thus far, to have borne any practical fruit. Without knowing of any previous ex-

periments with the elastic ligature, I began myself to experiment with it during the early part of the summer of 1890, hoping in this way to find a means of accomplishing the desired end of producing an anastomosis with previous adhesion of the intestinal surfaces. In my experiments, I tried three kinds of ligatures. One, a large, round rubber cord 4 millimetres in diameter, was speedily discarded. It was too large, was clumsy to tie; when tied it took up too much room and tore too big a hole through the intestinal wall. A second consisted of a flat rubber band 3 millimetres in width. This proved to be serviceable and can be advantageously used if the third variety cannot be obtained. The third kind, a rubber cord 2 millimetres in diameter, is that ordinarily used for the ligature of piles. It could not, for some reason, be obtained for my first experiments, but is to be preferred to all others on account of its smoothness, elasticity and great tenacity. By shaving the end of the rubber thin it may be drawn through the eye of a so-called worsted needle (a needle with a long eye) smaller than itself. This is a decided advantage for the reason that it is important to make as small a hole as possible through the intestinal wall, and also to have the ligature not only completely fill, but even to distend the hole so as to prevent any extravasation of feculent fluid. Now, by stretching the rubber during its passage and rendering it thin and small, it may easily be drawn after the needle, and its subsequent contraction will then largely increase its size and cause it to more than fill the orifice. The ligature in the most cases was passed through the gut in the direction of its long axis and at points most distant from the mesenteric attachment. Before passing it the bowels were stitched together by from three to six Lembert stitches, and afterwards similar stitches above the ligature served not only to give additional protection but also to bury the rubber in the intestinal folds. Usually an inch or more in length was included in the ligature. After the cord had been drawn through both coils of intestine it was tied as tightly as possible in a square knot. Although this knot will ordinarily hold without further fastening, yet as I wished to cut the ends very short in order to cause as little peritoneal irritation as possible, I always secured the ends so as to make slipping impossible. At first I did this by running a fine needle threaded with silk through the ends and thus tying them together, but as this procedure was awkward and consumed much time, I later on adopted a suggestion of my student, Mr. Hickey, and secured the knot by tying a silk thread, which was laid under it, first over the first turn of the knot and afterwards over the completed knot. This consumed almost no time and fastened the rubber securely against the possibility of accident. In making the knot, the

ligature should be drawn as tightly as possible without breaking.

The first effect of the ligation was to draw the intestines together into folds, and I was not a little apprehensive at first, lest these folds, agglutinated together, might be fixed in a permanent corrugation. In this I was agreeably disappointed. Examination of the intestines, even after so short a time as twenty-four hours, and before the ligature had made any perceptible progress in cutting through, would find these folds in process of obliteration. In some way the intestine accommodated itself to its new conditions and became speedily smooth and shapely. In some respects the early disappearance of these corrugations has been quite a puzzle, as I should have expected them to remain until the intestine was released from the binding cord. I feared, too, lest the ligation and folding of the intestinal wall might cause irritation or even obstruction of the gut. When we consider, indeed, the severity of the symptoms produced by the pinching of even a small segment of a gut in strangulated hernia, we might reasonably expect the occurrence of similar phenomena, with the extreme pinching of two adjacent intestines held together by a tightly drawn rubber ligature. This, however, never happened. Obstruction occurred in one or two cases from a too acute bending of an intestine, but the ligation itself seemed in no case to produce distress—even in gastro-enterostomy, where the involvement of the stomach in the ligature might warrant fears of an uncontrollable gastric irritability, this did not occur. The man upon whom I operated by forming a gastro-intestinal enterostomy for the relief of a pyloric cancer, vomited only once after the operation, namely, on the third day.

It is evident that the mere pinching or constriction of a portion of the intestinal wall is not in itself a cause of great irritation, provided the nutrition of the gut is not seriously interfered with. In fact, the symptoms which followed the operation seemed in no case to depend merely upon the injury done to the intestine. If the wound ran a perfectly aseptic course, the animals would show no distress whatever. If it became septic they would suffer accordingly. Every one who has operated on dogs, knows the difficulty of making and keeping them aseptic, especially in confined quarters. From lack of proper facilities I lost several animals from septic peritonitis. It was noteworthy, that the origin of trouble was rarely to be found at the seat of ligature or connecting with the cavity of the intestine, for the ligature, in fatal cases, was almost always found buried in the intestinal fold and progressing its usual course, while the distant peritoneal surfaces were covered with lymph or pus. In no case was there found any escape of feces or intestinal contents into the peritoneal cavity.

The normal course of the ligature and inclosed tissues, was about as follows:

Animal killed after twenty four hours, showed no change in the condition of the intestines operated on, except a partial obliteration of the folds caused by the ligature, and an adhesion of the adjacent peritoneal surfaces. No opening became as yet apparent at the seat of ligation. After forty-eight hours the intestines resumed their normal shape, all folds had disappeared, the adhesions had become firmer, and the rubber was seen to have slightly cut through the inclosed structures. At the end of seventy-two hours a free space usually appeared on each side of the ligature, through which water could be made to pass from one intestine into the other. The ligature still hung in the middle on uncut tissue. At the end of the fourth day, the opening became complete, the ligature disappeared and the anastomosis was accomplished. As the ligature cut through, the edges of the mucous membranes of each gut became glued together and united, and the result was a smoothed, healed edge all around the opening. The irritation caused by a rubber ligature in the peritoneum was just sufficient to cause adhesion of the surfaces with the intervention of hardly any appreciable amount of exudation. The length of the orifice formed was found to be equal to that of the tissue inclosed in the knot. Whether subsequent contraction with partial obliteration of the orifice, such as has happened after other methods of producing anastomosis would follow in course of time, is as yet uncertain. Variations were occasionally found in the course described. I have seen the opening completed at the end of the third day, and have seen it incomplete at the end of the fifth, but in general if the operation is done as I have described it, the result will be as I have stated.

In my first series of experiments I operated on twenty-four dogs, and then having become convinced of the perfect feasibility of the operation I chose it in preference to other methods, when called upon to establish an anastomosis between the stomach and small intestine, in a case of pyloric cancer.

Subsequently, seven dogs were operated on for the purpose of studying the effects of the operation in relieving intestinal fistulae and false anus, and eight others, for the production of fistulae between the gall bladder and small intestine. The history of the only case in which this method of operation has been thus far employed on the human subject is as follows:

Mr. Otto Cook, aged 59 years, a Belgian by birth, and a farmer by occupation, by the advice of his physician, Dr. Jno. Monaghan, since deceased, entered St. Mary's Hospital on January 8, 1891, to place himself under my care for cancer of the pylorus. He had been perfectly

well until three years ago, when he had begun to suffer from indigestion and occasional attacks of vomiting. The trouble gradually increased until he found himself during the last three months unable to retain any food whatsoever. He became gradually very weak, and at the time he entered the hospital was much emaciated. His breath was foul, and his food was vomited regularly a few hours after its ingestion. Examination revealed a tumor as large as a hen's egg, four centimeters above and four centimeters to the right of the navel. This tumor was immovable, and was evidently adherent to the adjacent structures.

January 9. The stomach was washed out with warm water and a large quantity of very sour, dark and offensive fluid mixed with mucus evacuated. After the hot water, a solution of boracic acid and bicarbonate of soda, eight grains of each to the ounce was injected and again evacuated. The patient experienced immediate relief from the nausea, and the procedure was repeated daily until January 12, the day of operation. As the diagnosis was not doubtful, the examination for hydrochloric acid was not made. The temperature during the time of his stay in the hospital previous to the operation ranged high, from 99.5° to 100.5° F. His pulse was steady at about 90 per minute. His bowels had been constive but were made to act by enemata, and rectal injections of bovine and brandy were given three times a day, to supply the much needed nutriment.

There were present at the operation Drs. H. O. Walker, F. W. Robbins, Pilcher, Irving, Monaghan and Mr. P. M. Hickey, Mr. A. J. Warren, and others. An incision was begun four centimeters above the navel, in the median line, and extended transversely to the left, for a distance of four inches. The pylorus was found to be as expected, the seat of a large tumor, adherent to the liver and absolutely immovable. Excision was out of the question and I proceeded to make an anastomosis with the small intestine. I tried first to find the jejunum by grasping it at its origin but failed to do so, and then followed Lücke's advice and grasped the highest coil of small intestine. As will appear later I had cause to regret this part of the operation. The omentum was very thin, atrophied and destitute of fat, and was pushed to the left. A small opening through its right border enabled me to bring the stomach into contact with the intestine, which was then sewed fast to it by six Lembert sutures in a line about four centimeters in length. A long worsted needle, armed with a long rubber cord, was then passed into and out of the stomach, the included space being about three and a half centimeters in length. It was then carried in like manner through the intestine and the ligature tied tightly and firmly in a square knot. The ends of the ligature, which were cut short, were

then secured by tying them together with a silk thread, which had been passed through them, and six Lembert sutures were inserted above. The stomach and intestine were thus fastened together by two rows of Lembert sutures, and by the rubber ligature which was between them and hidden from view, while the walls of the viscera were held by the ligature as in an ever tightening vise. The operation of anastomosis was conducted in this case very deliberately, and consumed after the exposure of the stomach eleven minutes of time. The most of this was occupied in passing the fine needle armed with the silk thread through the rubber in order to secure its ends. This is quite a delicate matter as the needle must be passed directly through the middle of the stretched rubber in order not to cut and weaken it as it would do if passed too near its edge. Since adopting the suggestion of Mr. Hickey, and securing the knot by tying the silk thread firmly around it, I have been able to materially reduce the time required for the procedure, and can now do it on the dog in less than three minutes.

The peritoneum, fascia and muscles, and skin were sutured separately, and the wound dressed with usual regard for asepsis. The patient reacted well and was given injections of bovine and brandy every six hours.

January 13. Injections continued. Temperature as before the operation ranging from 99.5 F. to 100.5 F. Pulse was stronger than before the operation. Patient had a tendency to slight hacking cough, no nausea, nor vomiting, nothing was given by the mouth.

January 14th. No pain, tenderness, nausea nor tympanites. Injections of bovine, brandy and tincture opii every four hours, mouth and tongue moistened with water, but no food nor drink. Morning temperature 100.5; evening temperature 103.8. Ten grains of quinine in half an ounce of whiskey were given by mouth and retained.

January 15th. Morning temperature 101; evening temperature 100.9; pulse 90 and good but patient felt very weak. The mouth and throat were dry and the cough troublesome. No expectoration, negative results on auscultation and percussion, complained of acidity. Is given teaspoonful doses of wine and water every fifteen minutes. For the first and only time since the operation, the patient vomited a mucus mixed with wine and water; the stomach was washed out with the boric acid solution.

January 16th. Morning temperature 100; evening temperature 101. Patient retained milk, bovine and wine in small quantities. Bowels moved at noon. The stool was thin, dark colored, and offensive. Ligature could not be found, wound was dressed for the first time and found to have healed by first intention. Bowels

moved three times on the night of January 16 and January 17. Nutrient enemata altogether discontinued; patient is weak and very homesick, and complains bitterly of his cough. Bismuth and saccharated pepsin grs. v was given every three hours. Morning temperature 99.5; evening temperature 100.

January 17th. Patient seems brighter and stronger. Pulse 90, good. Morning temperature 99; evening temperature 100. Milk, beef-tea and brandy are taken by the mouth and retained; no nausea nor distress. Cough is troublesome; bowels moved five times during the day; stitches were removed from wound which was entirely healed. The pyloric lump seems to have decreased in size.

January 18. Morning temperature 99; evening temperature 100.5. The cough is very annoying, but sounds are clear over both lungs. The cough is aggravated by drinking, but not by swallowing solids. He ate baked potatoes and soft boiled egg for breakfast, also some milk toast, but is dejected and homesick. Bowels moved six times since previous evening. The passages were dark and offensive.

January 19th. Morning temperature 99; evening temperature 100; cough much worse, but no expectoration. Mouth and throat are very dry. The throat is red but not swollen, and is covered with a white deposit, which, however, may be easily wiped off. Has difficulty in swallowing liquids but can take solids with ease. Throat was gargled with boric acid solution. Internally, tincture ferri chlorid. in five drop doses. Bowels have moved seven times since last evening.

January 20th. Morning and evening temperature 100. Patient is growing weaker and more homesick. Pulse 90, good; mouth is not quite so dry and throat is somewhat better. The pyloric tumor has apparently disappeared. Diarrhea continues. Twelve passages in the last twenty-four hours.

January 21st. No material change.

January 22d. Diarrhea continues and patient is growing weaker, but otherwise no marked change.

January 23. The patient insisted on going to his home twelve miles in the country, where he died on January 27, fifteen days after the operation.

On January 28th, I drove out with an assistant and succeeded in getting permission to examine the abdomen. It was found that the healing had taken place with absolute asepsis, the wound was firmly and completely united. There was no inflammatory exudate whatever in the abdominal cavity. The viscera all had their normal appearance except at the seat of disease. There was a pyloric tumor as large as a hen's egg firmly adherent to the under surface of the liver. In the mesen-

tery underneath there were numerous enlarged lymphatic glands. The stomach and underlying intestines were adherent by what may be called primary adhesion; that is, their surfaces were attached without any apparent deposit of lymph. I had feared on watching the case that I might have made the anastomosis too near the ileo-cæcal valve and in order to determine the exact position of the operation, I was obliged to separate the stomach from the surrounding mass. I found that the seat of anastomosis in the small intestine was about 91 centimeters (three feet) from the colon. The intestine above that point was empty; below it full of partly digested food. The cause of death was evidently inanition. In tracing out the intestine I unfortunately tore it partially apart from the stomach and thus spoiled the specimen. I found, however, that the anastomosis had been complete. In the stomach there were two holes through the mucous membrane and one through the muscular and serous coats. It was evident that in passing the needle into the stomach I had passed it too near the wall of that organ, and instead of clearing the mucous coat had pierced it, altogether, in four places, which made, on the completion of the anastomosis, two holes. This seemed to cause no difficulty in the passage of food but it taught me to enter the needle, in the future, into and to pass it out of the stomach more perpendicularly to the surface. In this way all such complications may be avoided. The orifices in the intestine and serous and muscular coats of the stomach were three and a half centimeters, (one and a half inches) long. That in the mucous coat of the stomach was as I have said divided in two by a small bridge of mucous membrane. It must be observed that neither in the stomach nor intestine nor peritoneal cavity was there the slightest appearance of inflammation. The edges of the opening between the cavities were healed and the mucous membrane of the small intestine was turned around the edge of the orifice and attached. The mucous membrane of the stomach, owing to the faulty course of the needle through it was stretched over the orifice and communicated with it by means of the two openings.

Although in transcribing this history I have not taken up space in relating unnecessary details of treatment, having given only the essential points, enough is nevertheless given to show conclusively that it is entirely practicable to produce intestinal anastomosis on the human subject by the elastic ligature. The failure of the operation was due, not to the method of making the anastomosis, which was highly successful, but to the misfortune of establishing it too low down in the ilium for the purposes of nutrition.

I wish to call especial attention to the following points:

1. The operation caused no irritability of the

stomach. He vomited only once after its performance, viz., on the third day after the operation, before the ligature had cut through.

2. The duration of that part of the operation, the uniting of the viscera and the formation of the anastomosis, was only eleven minutes, notwithstanding that it was done with more than necessary deliberation on account of its being the first case. It was, besides, unnecessarily prolonged by the method then adopted of fastening the ends of the ligature by transfixing them with needle and thread and then ligating. The method now adopted of securing the knot by simply tying a silk thread around it, will save many minutes.

3. Food began to pass from the stomach into the intestines at the end of the fourth day as shown by the complete tolerance of the stomach after that time. The accident of transfixing the mucous membrane of the stomach by carrying the needle too nearly parallel to its surface, made the orifice in that mucous membrane smaller than it should have been and may have delayed the establishment of the communication between the stomach and intestine.

4. The autopsy showed the anastomosis to have been completed with a minimum amount of irritation. I doubt whether it would be possible by any other method to produce so little disturbance.

Now, if we ask how far this method will meet the necessities caused by the various pathological conditions which produce intestinal stenosis, we will be enabled to come to a definite conclusion as regards its usefulness. It will be seen on consideration that like all surgical procedures, the method has its strict limitations. That which limits its applicability is the time which is required for the completion of the anastomosis. All cases of stenosis, therefore, which demand immediate relief or which must be relieved in less time than four days, must be treated by other methods, while on the contrary all cases of partial stenosis or even, as regards pyloric tumors and cancers, of complete stenosis in comparatively strong patients, may be operated on to advantage by this method. To particularize: the acute stenosis of volvulus or entanglement of Meckel's diverticulum with the intestine, or that caused by constriction by false membranes or by strangulated hernia or by intussusception, must be relieved by other means. In many of these cases an incision into the bowel which permits the escape of contained feces is a necessary part of the treatment and for all these, Senn's method or some one of its innumerable modifications would seem indicated. But in obstruction of the pylorus, when the patient has a fair amount of strength; in tumors of either intestine with partial obstruction; in the partial stenosis caused by wounds and injuries, in the narrowing of the gut by cicatricial contraction; in operations for the cure of false

anus and fecal fistule, and, finally, in impending mortification of the intestine in strangulated hernia, I believe that it will be found on trial superior in its ease of application, freedom from danger and efficiency, to any other method now in vogue. In tumors either of intestines or of neighboring parts pressing upon or involving the intestine, the symptoms of obstruction come on gradually. In all of these cases, early operations are indicated either for excision of the whole trouble, or if that is impossible for relief of the stenosis. In either case the production of anastomosis by ligature is especially indicated—in excision, after the tumor has been removed, the gut evacuated and the resected ends turned in.

Wounds of the large intestine are much more apt than those of the small, to give way and permit fecal extravasation. The thickness and comparative stiffness of its walls make a greater strain upon the Lembert stitches which hold the serous surfaces in contact, while the fecal masses, by their greater solidity, produce more friction in the bowel and a more prolonged and powerful impact upon the inner line of the wound. In the large intestine then it is especially desirable that the outer surfaces should grow together before the anastomosis is formed, and for that reason the operation by elastic ligature would seem to offer marked advantages over other methods. The lapse of four days before fecal matter could possibly exude, and during which the agglutination of the serous surfaces would become firm, would add no little to the security of the patient.

The advantage of the method in another class of cases, that of traumatic stricture of the small intestine, has forced itself upon my attention as I have compared the results of my operations on dogs with the history of a case of resection of the gut for traumatic stricture which occurred in my own practice. The case has already been published in the *Physician and Surgeon* for June and July, 1890, and I will give here only a résumé of it in illustration of the advantages promised over the old methods by the new one which I have suggested. On January 13, 1889, Barnard Burns, age 28 years, was struck violently in the abdomen by a falling log. Great pain, tenderness and tympanites ensued and lasted for three or four weeks. There then developed, gradually, a cicatricial contraction of the jejunum with its accompanying symptoms of partial obstruction, namely repeated attacks of great colicky pain with irritability of the stomach, and finally fecal vomiting. I operated on him on May 30, 1889, four and one-half months after the reception of the injury. I found the jejunum at one place contracted to such a degree that a lead pencil could not have been passed through it. The intestine had evidently been badly bruised, but not completely ruptured. Possibly one or the other of its coats had undergone ulceration

and absorption as the effect of the injury. I excised three inches of the bowel and joined the ends together with a double row of stitches, one for the mucous membrane and one for the muscular and serous coats. A contracted point in the mesentery which seemed to cause too much flexion of the intestine was also excised and reunited in a different way so as to relieve the flexion. The operation lasted one hour and a half, two-thirds of which time were occupied in the section and suture of the intestine. At its close he suffered greatly from shock, from which he did not recover until after the expiration of thirty-six hours. After that, he recovered without any further drawback.

What I wish to emphasize in this history is the fact that this patient was put in imminent danger of his life by the shock produced solely by the length and severity of the operation although everything else went well. In treating such a case again, I should first of all thoroughly and repeatedly wash out the stomach. This procedure has been shown, repeatedly, to relieve all of the symptoms of even acute and complete obstruction without, of course, curing the disease. The stomach and small intestine are thereby put in the same condition as the stomach in pyloric obstruction. The canal to the point of obstruction is emptied of all its contents, and the pain and intestinal tenesmus ceases as soon as the gut is allowed to rest. The reversed peristaltic action in these cases assists the surgeon in his efforts to relieve the intestine from the exhausting and futile efforts to force its contents beyond the point of constriction. Whether the small intestine could be thus relieved at whatever point in its length it should be constricted is yet to be seen. It is of undoubted service in constriction of the higher parts of the alimentary canal. In partial obstruction the relief given would doubtless be sufficiently great to permit the surgeon to treat the case on the same principles as in pyloric cancer, namely, to keep the mucous surfaces clean by frequent irrigation; to give by the mouth no food or drink at all or, if any, only such as could undergo immediate absorption; to nourish the patient by rectal enemata, and to reestablish the continuity of the bowel by forming an anastomosis of the part above with that below the stricture.

If I had, instead of excising the gut, passed an elastic ligature through the central and distal portions, immediately above and below the constriction, I could have accomplished in a few minutes what occupied a whole hour, and saved the patient the enormous shock to which he nearly succumbed.

Although I have not ventured to recommend this procedure in cases of acute and complete obstruction, I am nevertheless by no means sure that it may not prove to be the best and most promising of all operations in acute and irremedi-

able obstructions of the jejunum and duodenum if the case is operated on early, before the patient has become exhausted. It must be insisted on that all such cases shall be treated, before and after the operation, by the frequent washing out of the stomach with the rubber syphon, and that alimentation shall be accomplished solely through the rectum.

Another class of cases in which this operation may be expected to be of great utility is that which includes gangrenous hernia, fecal fistula, and artificial anus. It occurred to me in thinking over the various methods of treating the mortified intestine in strangulated hernia that the cure of the false anus which results in such cases might be anticipated by making at once an anastomosis between the afferent and efferent limb of the gut in sound tissue. By passing the elastic ligature through the two portions of gut an orifice of communication would be formed at the end of the fourth day, and with a new channel for the passage of feces. The false anus would be in condition to be healed with comparatively simple means.

I operated on my second series of dogs, seven in number, with the purpose in view of studying the results of such procedures. The experiments had as yet yielded no practical results on account of the great mortality of the animals from septic peritonitis, when I received the second part of the forty-first volume of the *Archives für Klinische Chirurgie*, containing an article by Prof. Helferich, of Griefswald, entitled "Ausführung der Herniotomie bei der Gangrän verdächtigen Darm." I found myself anticipated in the idea and practice by Prof. Helferich, who had already operated on and recorded two cases of this kind, in which, however, he had made the anastomosis by incising and stitching the intestines together. One of the two cases was successful. Some feces passed for a few days, in small quantities, through the false anus, although the greater part was evacuated through the rectum. On the ninth day the protruding perforated coil of intestine was excised, and the cut ends turned in and sutured. A small remaining fistula required a further and final operation for its relief. The second case ended fatally in collapse.

I think that every one who considers for a moment the condition of things in a gangrenous hernia will see the advantage of this operation. I should not, however, subject a patient to the long, tedious, and dangerous operation of forming an anastomosis after any of the old methods. In these cases, when once the constriction of the hernia is relieved, the operation by elastic ligature could be accomplished within five minutes. It would indeed require four days to establish the communication between the intestines, but the patient could well afford to wait for that when by so doing he could escape the dangers of collapse

and shock, to be expected of any long operative procedure under such circumstances.

As for already existing fecal fistula and false anus, in which milder measures have failed, it would be proper to try the effects of the elastic ligature in either one of the two ways: First of all the ligature might be used to destroy the projecting spur, which in so many cases of artificial anus separates the afferent from the efferent gut. The patient should be put in Trendelenburg's posture, with elevated hips, to permit the intestines to fall away from the seat of operation. The needle armed with the rubber ligature should then be passed as deeply as possible through the spur and tightly tied. The spur destroyed, the case could then be treated on general principles. If the formation of the spur should be such as to render this maneuver impossible, or if the case were one in which no spur existed, the abdomen could be opened and an anastomosis be formed by the ligature between the afferent and efferent limbs of the gut. There can be no doubt that relief might be given in this way to many otherwise incurable troubles of this kind. Besides these operations on the intestine, I made some experiments with the view of making communications in the same manner between the gall-bladder and the small intestine. In doing so I met with difficulties which did not occur in the operations on the intestines. The liver and gall-bladder in dogs, owing to the narrowness of the thorax, is somewhat difficult of access, and the constant, and often violent, motion of the diaphragm as the animal struggles, vomits, or barks, prevents that delicate manipulation which is essential to success. These impediments might, it is true, be overcome by a sufficiently large abdominal incision, but this in turn causes greater danger from shock and septic poisoning. The operations were conducted in the same manner as in intestinal anastomosis, except that the lesser size of the gall bladder made it necessary to include less tissue in the ligature. Whereas in the intestinal anastomosis the thread inclosed from three to four centimeters in length; in the experiments on the gall bladder and duodenum there were included only one and a half or two centimeters of surface.

Another difference in these operations was the tendency of the bile to escape alongside of the ligature into the peritoneal cavity, an accident which never happened with the contents of the intestine. This was due both to the thinness of the wall of the gall-bladder and the thinness of the bile, and added an additional danger to these operations. Nine dogs were operated on, of which six died. One from intestinal hæmorrhage, one from a flexion of the duodenum, two immediately after the operation, apparently from shock, and two from septic peritonitis. Of the three that lived, one lived sixteen, one fourteen, and one

twelve days before they were killed for examination, and I hoped to prove the operation to be practicable. In this, however, I was sadly disappointed. In two of the three the ligature had disappeared, but the orifice of communication had disappeared with it, and there was nothing left to mark the spot of operation but the scar. In the third the ligature was found in place. It had cut through the intervening tissues, but had been prevented from escaping by the surrounding structures, which had contracted around it and enclosed it. It could not be doubtful that this orifice, too, would have closed like the others by cicatricial contraction as soon as it had been made possible by the escape of the rubber.

I had not, until this time, been aware that Dr. Gaston, of Atlanta, had anticipated me in this kind of work, but learned of the fact from Dr. Senn. Dr. Gaston kindly sent me the papers, excepting the first, which he had published on this subject, beginning in September, 1884. Dr. Gaston endeavored to establish fistulae between the gall-bladder and duodenum by the use of a ligature, sometimes of silk and sometimes of rubber. The main features of his method were the same as those of my own. The gall bladder was fastened by Lembert sutures to the intestine, the ligature passed through both viscera and tied, and other Lembert sutures again above and around the ligature. Many of his operations were complicated by the ligation of either the hepatic, cystic or common gall ducts, and in all of them, as nearly as I can judge from the description given, the amount of tissue included in the ligatures was much less than in my own experiments. His very interesting experiments were the first of their kind, and he can undoubtedly claim the priority in the attempts to make channels of communication between hollow viscera by means of ligatures, although I cannot learn that he ever attempted to do so for any other purpose than to make a duodeno-cholecystostomy.

I wish that I could say that either his efforts or my own, had resulted in the establishment of a practicable procedure for this purpose. The results of our experiments in this direction at present, show only this: that it is possible by the use of a ligature to make a communication between the gall-bladder and duodenum which may last for two or three months, but that the procedure is so exceedingly dangerous as to be inadvisable on the human subject. The most of the animals operated on, died, and from causes which we might not be able with all care to avoid. It is exceedingly difficult to prevent the escape of bile into the peritoneal cavity through the hole made by the ligature, and this, although not necessarily fatal, is nevertheless a grave complication, if for no other reason than that it interferes greatly with that union by first intention,

which is an essential element of success in this method. Besides, the adhesion of the surfaces, the escape from all fatal complications, and the division of the inclosed structures by the ligature does not insure the establishment of the fistula. In the three cases of my own which lived, the ligature had cut through, but the contraction of the tissues had already, in less than seventeen days, obliterated the orifice, which it had made, although not less than one and a half centimetres of length of surface had in each case been included in the ligature. It is possible that the total obstruction of the cystic or common duct might ensure a greater permanency of such a fistula. In one of Dr. Gaston's cases, the fistula persisted for nearly three months, but it must not be forgotten that the obstruction of the common duct would add greatly to the danger of the operation, as it would cause an enormous distension of the gall-bladder with extreme thinning of its walls, and a constant pressure, which would cause a continuous current of bile through the holes made by the needle and thread, and, if it did not produce a fatal peritonitis, would almost inevitably prevent union between the gall-bladder and duodenum.

I would not be understood as despairing altogether of this method for the formation of a fistula between the gall-bladder and duodenum, although the method of incision and suture seems to me to be safer, but I cannot regard it yet as a justifiable operation, whatever may be its future after further experimental study. In one respect I should differ from Dr. Gaston. The pathological conditions, which would make duodeno-cholecystostomy proper, are such as are constantly recurrent. For that reason, indeed, Langenbuch recommended the excision of the gall bladder, in order to prevent the formation of gall stones, and render the cure permanent. It should therefore be the aim of the surgeon to make any fistula that he might establish enduring. This can only be hoped for if the opening between the viscera is originally very large; even then it is probable that the tendency to contraction in so loose a structure as the gall-bladder would be greater than the tendency to keep the communication open. When, therefore, Dr. Gaston says, commenting on one of his cases: "Upon stitching up the duodenum to the point of opening, it was evident that too much tissue had been included in the ligature, as the orifice was unnecessarily large; and in repeating this experiment I would suggest that the needle and ligature should only include so much of the respective wall as to secure an orifice from the cavity of the gall bladder into the alimentary canal," he would seem to me to be urging a practice which would defeat its own ends. While it is not impossible that a small fistula would remain indefinitely open, to make that event even

slightly probable, the orifice should be made as large as possible.

It is not only in fistulas of the gall-bladder that this tendency to contract has been remarked, but also in those of the stomach and small intestine. In one case an opening of three centimeters in diameter between the stomach and small intestines had contracted in five months and a half to less than half a centimeter, and in another case an orifice an inch long, had altogether closed in four months (Weir).

It becomes important, therefore, to study the conditions which favor, and those which oppose this undesired process of healing. It can hardly be doubted that a large opening would be less likely to close than a small one, and large orifices may be made by all methods, by that of the ligature as well as by others. There are probably other circumstances, however, which also influence the result. One of these must be the greater or less perfection with which the mucous coats are united, for if in any case union takes place between the outer surfaces while the mucous membranes are left unattached, a line of granulating tissue would occupy the inner edge of the orifice which might be expected to subsequently indefinitely contract, whereas an opening lined by a continuous layer of mucous membrane would tend to retain its shape and size; so, too, any great inflammatory deposit on the outer surface would tend to produce the same result of contraction and obliteration of the orifice.

It is not then a matter of indifference, by what means the communication is completed. Experience alone can determine the value of the different methods in this respect, but after careful study of pathological specimens from my own cases, I feel hopeful that my method will prove of especial value in making permanent openings between the viscera, for I have noticed first of all, that during the process of absorption from the pressure of the cord the mucous membranes are forced in on both sides until they meet, so that the ligature leaves behind it a smooth edge covered with the inner lining, and second the irritation of the serous membranes by the ligature is just sufficient and no more than to cause adhesion. In some of my experiments I used silk ligatures instead of rubber and found that they too would cut through the tissues and leave an opening. In many ways, however, they were inferior. They would soon lose their antiseptic qualities, act as setons and cause too much inflammation. There were therefore more failures, and owing to the too great deposit of lymph the intestines were apt to remain puckered up with a small contracting opening, instead of a large one. The rubber, on the contrary, causes barely enough irritation to cause union of the serous surfaces.

In conclusion, then, I will sum up the matter as follows:

1. Rubber ligatures can be used advantageously in many cases to produce anastomosis between two hollow viscera.

2. They are adapted for all chronic cases, in which it is possible to wait four days for the completion of the opening.

3. They are contraindicated in all cases of acute obstruction which demand immediate relief.

4. In using them for this purpose they should be passed through the opposing viscera in such a way as to include all of the intervening tissues, serous and muscular coats and mucous membranes in one tight knot.

5. Union takes place between the serous surfaces after the application of the ligature by primary adhesion with a minimum amount of irritation.

6. The method of thus producing an intestinal anastomosis excels all others in the rapidity of its execution and in its freedom from danger of shock, fecal extravasation and septic poisoning. Its sole drawback is the length of time required for its completion. I shall be glad if the profession will give it a trial in appropriate cases.

I take pleasure in acknowledging my indebtedness to Drs. Ives and Ireland and Messrs. Hickey and Warren for their assistance in making the necessary experiments.¹

FRACTURE OF THE ASTRAGALUS. WITH IRREDUCIBLE DISPLACEMENT OF THE FRAGMENT.

A Paper read before the Fourth Annual Meeting of the National Association of Railway Surgeons, held at Buffalo, New York, April 30, and May 1 and 2, 1897.

BY R. HARVEY REED, M.D.,

UNIVERSITY PARK, MANSFIELD, OHIO.

PRESIDENT CENTRAL OHIO MEDICAL SOCIETY; SURGEON BIRMINGHAM & OHIO R. R.; MEMBER NATIONAL ASSOCIATION OF RAILWAY SURGEONS, AMERICAN MEDICAL ASSOCIATION; FRENCH MEDICAL ASSOCIATION; AMERICAN PUBLIC HEALTH ASSOCIATION; HONORARY MEMBER D. HAVLS AUSTRIAN SURGICAL SOCIETY, PHILADELPHIA; TEXAS STATE MEDICAL SOCIETY, ETC.

Fractures of the astragalus as compared in frequency with fractures of the other tarsal bones, are comparatively rare; whilst fractures of this bone with irreducible displacement is still more uncommon.

This bone being largely composed of cancellated tissue, and quite irregular in form, and surrounded with numerous articulations, affords it a greater immunity from injury, than almost any other one of the tarsal bones.

In fact, little is said in our text-books regarding this important complication, which to the railroad surgeon is of double importance, owing to the permanent injury it produces, and the con-

¹ The rubber ligatures can be procured of Milburn & Williams, Detroit, Mich.

sequent dangers this form of injury is liable to entail on the railroad company.

Hamilton, in his work on "Fractures and Dislocations," reports ten cases of fracture of the astragalus, nine of which were caused by a fall, and one by crushing. In the former the force was largely reflected to the foot, and conducted to the astragalus through the tibia, causing the fractures, some of which were followed by displacement of the fragments.

Ashhurst says it is almost invariably broken, by the patient falling from a height and alighting on his feet; and that he only knew of two cases, where there had been a fracture of this bone, with displacement of the fragment; the one was a case reported by himself, the other by Dr. Norris.

Agnew, in referring to fractures of the tarsus, reports seven fractures of the astragalus; 14 of the calcaneum, and 25 of the other bones of the tarsus; which shows that fractures of the astragalus only occur in 15 per cent. of all the fractures of the various bones of the tarsus.

Longsdale, Croly, Neill, Bryant, Vollmar, MacCormac, M. Tavignot, Malgaigne, M. Rognetta, Sir Astley Cooper, Clark, Norris, Goyder and John Ashhurst, Jr., each report a case of fracture of this bone; whilst Sheppard reports having observed four fractures of the astragalus, and Mr. Erichsen two.

The testimony of these surgeons, proves that it is usually caused by falling, in which the patient alights on some solid substance on the feet, whereby the force of the fall is extended to the astragalus which may cause a simple fracture, with or without dislocation of the fragment, or a comminuted fracture with or without displacement of the fragments, or a compound comminuted fracture, with or without displacement of the fragment or fragments. The fragment or fragments may be dislocated anteriorly on the dorsum of the foot, or downward and forward, or downward, outward and backward under the internal malleolus; and one case is reported, in which the displaced fragment found its way to the plantar surface of the foot.

There is no certainty as to the direction of the line of fracture, which is as varied as the force or forces that produce it.

The reduction of these displaced fragments is quite a difficult task, which is usually attended with absolute failure, especially when they are displaced downward and backward under either of the malleoli, and whilst Dr. Ashhurst reports in the *American Journal of Medical Sciences*, for April, 1862, of having been able to replace a dislocated fragment of a fractured astragalus, yet I believe he is the only surgeon who has been able to do so (and has reported the case), to the best of my knowledge at least.

The anatomical relations of the astragalus are

such, that when displacement of a fragment after a fracture occurs, it makes it evident at a glance, that its reduction will be attended with great difficulty; especially when we consider its shape and structure, together with the numerous ligaments and articular surfaces it presents; yet, notwithstanding all this, I consider it good surgery to make an honest and carefully conducted effort at reduction by trying to so manipulate the parts as to give the least possible resistance to its return; the particular manipulation of which, will depend largely upon what part of the bone is fractured and displaced, and where it is lodged. Operative interference for the removal or reduction of the bone, especially after prolonged and diligent efforts had failed to replace it, would very naturally present itself to our minds next. In this connection, we can find but little data to guide us; whilst Bryant and Wythe operated and removed the displaced fragment with recovery, yet, on the other hand, a similar case operated by Dr. Norris, died. These, in the absence of additional reports, would show a mortality of 33 per cent. against 66 per cent. of recovery, and at a time when at least two of these cases ('Norris' and Bryant's) were undoubtedly operated prior to the use of antiseptics, and whilst we have no assurance that Wythe's was, although it is more probable than either of the other cases.

Some operators advise the replacement of the dislocated fragment, others, the removal of the entire astragalus (which was done in Wythe's case), whilst others only advise the removal of the displaced fragment. But when we consider the structure of the bone, which is made up largely of cancellated tissue, and consequently more vascular, and hence the remaining portion of the bone is more liable to take on destructive inflammation on the one hand, whilst the replaced fragment is liable to become necrosed on the other, owing to the interference with the blood supply, as well as the danger of the introduction of septic germs, which makes the question of replacement by operative interference a doubtful procedure.

Again, if the displaced fragment is allowed to remain out of place, it not only makes a permanent deformity, but a permanent disability; but on the other hand, if you attempt to remove only the fragment, you take the chances of disease of the remaining portion of the bone following, and if you remove the entire bone there is more or less permanent deformity and disability from that. From this it would seem as though this injury produced a fair example of the old adage of:

"Damned if you do, and damned if you don't.
Damned if you will, and damned if you won't."

From this it would appear that we are left to the choice of four or five evils: 1. If the fragment can't be reduced by manipulation (except-

ing in compound or compound comminuted fractures) to simply let it alone, and take the chances of it becoming encysted.

2. To remove only the displaced fragment, by cutting down on it, and extracting it antiseptically.

3. To remove the entire astragalus.

4. To replace the displaced fragment, and take the chances of inflammation and destruction of both the hard and soft structures of the surrounding tissues.

5. To remove the displaced fragment and thoroughly cleanse the cavity it left, and put all the surrounding parts in a strictly aseptic condition, after which, pack the cavity with Semm's antiseptic decalcified bone chips, which I believe is better than replacing the detached fragment of bone; as it is very hard to make this strictly antiseptic, whilst the decalcified bone chips are, and hence less liable to set up infection in the surrounding parts.

REPORT OF CASES.

Case 1.—George M., æt. 55, an amanuensis; on August 12, 1885, was riding with a friend in a delivery wagon, when the horse took fright and started to run away. Mr. M. became alarmed, and jumped out of the wagon on the paved street, sustaining a fracture of the astragalus of the left foot, with displacement of the fragment downward and backward under the malleolus; the internal fragment was also slightly displaced backward and inward, thus lengthening the lateral diameter of the ankle quite considerably. The foot and ankle soon swelled up and became very painful; a physician was called who pronounced it a *bad sprain* of the ankle, and treated it accordingly.

Some months subsequently the writer was called and found a fragment of the astragalus, about two inches in length, and nearly as wide, lodged under the left external malleolus; whilst the depression caused by the displaced fragment was easily detected, just beneath, inward and in front of the fibula. All attempts at reduction were without avail; but notwithstanding the marked deformity, the patient could use his foot fairly well and had quite a considerable degree of motion; but it was more or less painful and was a source of inconvenience to him all the time, and especially so in changeable weather. Later on necrosis of the external metatarsal bone set in, and at one time it was thought that the entire foot would have to be amputated; an excision, however, of the external metatarsal was all that was necessary; since which time, he has had but little trouble with it, other than what we have already mentioned.

Under all the circumstances, I considered that conservative surgery in his case was a choice of the least evil, and hence refrained from excising

the displaced fragment. The result is that this patient is now able to walk all over the city with the aid of a cane, and whilst his foot and ankle is stiff and clumsy, I believe it is better than to have risked an operation for its removal.

Case 2.—Chas. S., æt. 29, a brakeman in the B. and O. yards at Mansfield, O., was thrown off the top of a box-car by a broken brake May 13, 1889, alighting on his feet on the end of a tie; sustaining a fracture of the astragalus of the right foot, with displacement of the fragment underneath the internal malleolus.

I was called shortly after the accident, and readily diagnosed the nature of the injury, as I could easily feel the displaced fragment beneath the internal malleolus, whilst beneath and in front of the internal half of the tibia, I could readily discover the depression left by the escaped fragment of bone. In addition to this there was some spreading of the tibia and fibula, thus materially increasing the lateral diameter of the ankle; no doubt due to the tearing of the ligaments, and the strain produced by the fall, together with the escape of such a large fragment of bone, with its associate weakening of the surrounding parts.

Here again we were confronted with the question of an operation for the removal of the displaced fragment of bone, which no ingenuity or manipulation the author could devise, was able to replace.

In its present location we recognized a degree of support to the tibia, being lodged immediately underneath the internal malleolus, which support would be lost by its removal, saying nothing of the danger attending the operation to the surrounding structures; and again, conservatism got the better of us and we decided to let well enough alone. The result is a more or less painful ankle at times, with considerable loss of motion, and some deformity; but otherwise, a fairly good foot and leg which enables him to walk reasonably well and earn a good livelihood for his family.

Case 3.—Harry D., a stonemason, æt. 33, jumped off a freight train when it was in motion, October 8, 1889, and lit with one foot on the end of the tie, producing a fracture of the astragalus of the right foot, with displacement of the fragment underneath the external malleolus. The author was called to see the patient a short time after the injury, and found a fragment of the astragalus some 2 inches in length by 1 inch in width, lodged just beneath and slightly posterior to the coronoid process of the fibula. A marked depression was observed just below, in front and internal, to the external malleolus, which was evidently the nidus of the displaced fragment of the bone. In the absence of sufficient data to encourage an operation, and with the dangers that might attend such staring me in the face, I again resolved to pursue the conservative method of treatment, until something better presented it-

self to my mind as unquestionably an improvement on the conservative methods I had thus far been forced to adopt.

The results in this case are much better than either of the former cases. The patient has little or no pain, except when the weather changes, and is not inconvenienced to any extent; can walk with limping but little, and is regularly following his daily avocation as a stone-cutter.

The following interesting case was kindly given me for this paper, by my friend Prof. Thorne, of Toledo, O., Surgeon in Chief of the Toledo, St. Louis and Kansas City R. R.:

Case 4.—H. F., a German, æt. 32, weighing about 200 lbs., a lager beer brewer, and given to the liberal use of this fluid, whilst at work slipped from the lower round of a ladder, alighting upon a wet floor. The peculiar position of landing, together with the great weight of the patient, were such as to result in a fracture of the astragalus of the left foot, forcing the outer half out from its normal position, and causing quite a prominence over the outer portion of the dorsum of the foot.

A corresponding diagnosis was made, and the injury treated accordingly. In about thirty days after the accident, complete death of the overlying structures ensued, necessitating the removal of the displaced fragment of bone. This was followed by decomposition and infection, which was no doubt encouraged by his constitutional condition, and the result of his intemperate habits, until it was necessary to amputate his leg below the knee, in order to save his life.

Here we have a case where conservative surgery was followed with disastrous results which probably lost the patient his foot.

In summing up the testimony of this unfortunate injury, we have found that, in fractures of the astragalus with displacement of the fragment:

1. That reduction is the rare exception, and not the rule.
2. That total failure to reduce the fragment, is the general rule in this class of cases.
3. That these cases may get well with a fairly good and useful ankle by following a conservative method of treatment.
4. That a conservative line of treatment may be followed with disastrous results.
5. That a fair degree of recovery may follow the excision of the dislocated fragment.
6. That destructive inflammation of the remaining portion of the astragalus may follow with necrosis, necessitating its ultimate removal.
7. That a fracture involving any considerable portion of the astragalus, with displacement of the fragment, is practically if not almost invariably followed with a permanent and irreparable injury; for if resolution follows without an operation, there is a permanent deformity with associate disability, or if the fragment is removed and

the patient recovers, there is a permanent disability; or if the entire astragalus is removed, as advised by some authors, there is still a fixed disability.

It seems to me that *one* of the plain lessons we are to learn from the study of these cases, is to be very guarded in our prognosis, in fractures of the astragalus with irreducible displacement of the fragment; for if we are not, we may rue our rashness under the lash of chagrin and disappointment.

Another plain lesson seems to be stamped upon the clinical history of this class of cases; and that is, to be equally guarded in operating them, as you are in projecting your diagnosis.

But, when an operation for the removal is your plain duty, do it promptly, under the strictest antiseptic precautions, and if you have any doubt as to the danger of necrosis of the remaining portion of the bone, remove that also. Where this is not evident, it might be well to consider the advisability of packing the cavity produced by the displaced fragment of bone, after thoroughly cleansing it, with Senn's decalcified bone chips, being careful to remove all the synovial membrane before packing the cavity; for the use of these decalcified bone chips as used by Prof. Senn, after the removal of portions of dead bone, has been so satisfactory, that we believe their use in this class of cases would be followed by satisfactory results also.

Mansfield, O., April 20, 1891.

LECTURES.

THE CHEMICAL FACTORS IN THE CAUSATION OF DISEASE.

A Course of Three Lectures delivered at the Post-Graduate Medical School of Chicago, March 2, 27 and 28, 1891.

BY VICTOR C. VAUGHAN, M.D., Ph.D.,

OF ANN ARBOR, MICH.

PROFESSOR OF HYGIENE AND PHYSIOLOGICAL CHEMISTRY AND DIRECTOR OF THE HYGIENIC LABORATORY IN MICHIGAN UNIVERSITY.

(Continued from page 670.)

LECTURE III.—THE AUTOGENOUS DISEASES.

All living things are composed of cells. The simplest forms of life are unicellular, and in these all the functions of life devolve upon the single cell. Absorption, secretion and excretion must be carried on by the same cell. A collection of unicellular organisms might be compared to a community of men with every individual his own tailor, shoemaker, carpenter, cook, farmer, gardener, blacksmith, etc. However, only the lowest forms of life are unicellular; all others are multicellular. In the higher animals there is a differentiation not only in the size and structure of the cells, but in the labor which they perform. The body of man may be compared to a

community in which labor has been specialized. Certain groups of cells, which we designate by the term "organ," take upon themselves the task of doing some special line of work, the well-doing of which is essential to the health, not only of that group, but of other groups as well, or of the body as a whole. There is an interdependence among the various organs. Certain groups of cells supply the fluids or juices which act as digestants, and among these there is again a division of labor. The salivary glands supply a fluid which partially digests the starch of our food; the peptic glands supply the gastric juice which does the preliminary work in the digestion of the proteids; while the pancreatic juice completes the digestion of the starches begun in the mouth, of the proteids begun in the stomach, and does the special work of emulsifying the fats. But even some of these products of complete digestion would be harmful should they enter the circulation unchanged. The peptones must be converted into serum-albumin by the absorbing mechanism of the walls of the intestines, and while to per cent. of the fat of the food is split up into glycerine and fatty acids by the action of the pancreatic juice, a much smaller per cent. enters the thoracic duct in this divided form. The food may be taken in proper quality and quantity; the digestive juices may do their work promptly and properly, but if the absorbents fail to perform their functions properly, disease results. It may happen that the failure lies in improper or imperfect assimilation and the result becomes equally disastrous, and with the effects of non-elimination we are fairly conversant. Of the myriads of cells in the healthy human body there are none which are superfluous. It is true that among these ultimate entities of existence, death is constantly occurring, but in health regeneration goes on with equal rapidity and each organ continues to do its daily and hourly task. The microscope has made us familiar with the size and shape of the various cells of the body, and the students of pathology have described the alterations in form and size characteristic of various diseased states. But we must remember that in the study of these ultimate elements of life there are other things, besides their morphological history, to investigate. They are endowed with life, and they, as well as the germs which we have been studying, have a physiology and chemistry which we know but slightly. They are influenced beneficially or harmfully, as the case may be, by their environment. They grow and perform their functions properly when supplied with the needed pabulum. They are not immune to poisonous agents. They are injured when the products of their own activity accumulate about them.

The object in writing this lecture has been to collect what evidence I may concerning those dis-

eases which arise from imperfect or improper activity of the cells of the body, not due to the introduction of foreign cells. To designate this class of diseases I have selected the word *autogenous*, and I understand that in these diseases the *materies morbi* is a product of some cell of the body, and not, as in the case of the infectious diseases, of cells introduced from without the body.

It is true, without exception so far as I know, that the excretions of all living things, plants and animals, contain substances which are poisonous to the organisms which excrete them. A man may drink only chemically pure water, eat only that food which is free from all adulterations, and breathe nothing but the purest air, free from all organic matter, both living and dead, and yet that man's excretions would contain poisons. Where do these poisons originate? They are formed within the body. They originate in the metabolic changes by which the complex organic molecule is split up into simpler compounds. We may suppose—indeed, we have good reasons for believing—that the proteid molecule has certain lines of cleavage along which it breaks when certain forces are applied, and that the resulting fragments have also lines of cleavage along which they break under certain influences, and so on until the end products, urea, ammonia, water and carbon-dioxide are reached; also that some of these intermediate products are highly poisonous has been abundantly demonstrated. The fact that the hydrocyanic acid molecule is a frequent constituent of the leucomaines is one of great significance. We know that chemical composition is an indication of physiological action, and the intensely poisonous character of some of the leucomaines conforms to this fact. It matters not whether the proteid molecule be broken up by organized ferments, bacteria, or by the unorganized ferments of the digestive juices, by the cells of the liver or by those still unknown agencies, which induce metabolic changes in all the tissues—in all cases poisons may be formed. These poisons will differ in quality and quantity according to the proteid which is acted upon, and according to the force which acts.

Peptones formed during digestion do not in health reach the general circulation. When injected directly into the blood they act as powerful poisons. They destroy the coagulability of the blood, lower blood-pressure, and in large quantities cause speedy death. Brunton attributes the lassitude, depression, sense of weight in the limbs and dulness in the head occurring in the well-fed, inactive man, after his meals, to poisoning with peptones. The remedy, which he proposes, is less food, especially less nitrogenous food, and more exercise. That some substance resulting from the proteids of the food is the

cause of this trouble Brunton thinks is evidenced by the fact that the weakness and languor are apparently less after meals consisting of farinaceous foods only.

That peptone finds its way into the general circulation frequently is shown by its detection in the urine in many diseased conditions, some of which are infectious and others autogenous in character. However, propeptonuria, or albumosuria, is more common than peptonuria, and we have already seen that many of the bacterial albumoses are among the most highly poisonous bodies known, but the action of the albumoses formed during digestion has not, so far as I know, been studied. The valuable work of Kühne and Clittenden on the chemical character of these bodies should be supplemented by a thorough investigation of their physiological effects when injected into the blood. It is more than probable that valuable information would be secured by such studies. That albumose is frequently found in the urine is shown by the following list of diseases in which it has been observed, given in the last edition of the work of Neubauer and Vogel on the urine. Kössner has found it in spermatorrhœa; Köppen, in mental diseases without spermatorrhœa; Kahler, in osteomalacia; Bence Jones, in multiple myeloma; Senator and others, in dermatitis, intestinal ulcer, liver abscess, croupous pneumonia, apoplexy, vitium cordis, resectio coxæ, parametritis, endocarditis, typhoid fever, nephritis, phthisis, etc.; Loeb, in measles and scarlet fever; Leube, in urticaria; and Lassar, after inunctions of petroleum. Köttwitz, Fürst! er and others find albumose frequently in the urine in mental diseases. Evidently, there is much to learn from the study of the conditions accompanied by the elimination of the albumoses in the urine. It is more than probable that the acute Bright's disease following scarlet fever, diphtheria, and the other acute infectious diseases, owes its existence to the poisonous albumoses of these diseases. Prior has recently shown that undigested egg albumin is sometimes absorbed and produces marked disturbances. A boy, after eating sixteen raw eggs, had a high fever accompanied by the appearance of both albumin and hæmoglobin in the urine.

Brieger obtained by digesting fibrin with gastric juice a substance which gives reactions with many of the general alkaloidal reagents and to which he has given the name "peptotoxine." A few drops of a dilute aqueous solution of this substance sufficed to kill frogs within fifteen minutes. The frogs became apparently paralyzed and did not respond to stimuli. Slight tremor was perceptible in the muscles of the extremities. Rabbits of about one kilogram weight were given from 0.5 to 1 gram of the extract subcutaneously. About fifteen minutes after the injection, paralysis beginning in the posterior ex-

trémities set in: the animal fell into a somnolent condition, sank and died. In some rabbits several hours elapsed before the above mentioned symptoms appeared.

Peptotoxine was found by Brieger to be formed not only by the digestive juice, but to be among the first putrefactive products of proteins, a-fibrin, casein, brain substance, liver and muscle.

It is highly probable that many of the nervous symptoms which accompany some forms of dyspepsia are due to the formation and absorption of poisonous substances.

In some persons the tendency to the formation of poisons out of certain foods is very marked. Thus, there are some to whom the smallest bit of egg is highly poisonous; with others, milk will not agree; and instances of this kind are sufficiently numerous to give rise to the adage, "what is one man's meat is another man's poison."

Brunton is of the opinion that the condition which we term "biliousness," and which is most likely to exist in those who eat largely of proteins, is due to the formation of poisonous alkaloids; but of this we have no positive proof.

Whether or not the unorganized digestive ferments ever find their way into the blood in quantity sufficient to cause deviations from health, we are not in a position to state definitely. The older physiological chemists teach us that pepsin and trypsin are frequent, if not constant constituents of normal urine, but their experiments were made without any reference to the possibility of the ferments which they found being formed by the bacteria of the urine, and after carefully going over the literature of the subject I am not prepared to pass judgment on the truth of their statements. However this may be, the fact that these ferments manifest a marked toxicological effect when introduced into the blood is of great interest, especially at this time. Hildebrandt has recently reported the results of some experiments made by himself upon this subject. He finds that a fatal dose of pepsin for dogs is from 0.1 to 0.2 gram per kilogram of body weight. The subcutaneous injection of these quantities is followed by a marked elevation of temperature, which he designates as "ferment fever." This fever begins within an hour after the injection, reaches its maximum after from four to six hours, and may continue for some days. On the day preceding death, the temperature generally falls below the normal. During the period of elevation there are frequent chills.

The symptoms which accompany the fever vary somewhat with the species of animal. Rabbits lose flesh notwithstanding the fact that they continue for a while to eat well, become very weak and death is preceded by convulsive movements. Dogs tremble in the limbs, become uncertain in gait, and vomiting, dyspnoea and coma are followed by death.

On section there is observed parenchymatous degeneration of the muscles of the heart, and similar changes in the liver and kidney. There are abundant hæmorrhages in the intestinal canal, in Peyer's patches, in the mesenteric glands; and in the lungs in cats. Thrombi are frequently found in the lungs, and in some cases in the kidneys.

The effect upon the coagulability of the blood is worthy of note. At first there is a period during which the coagulability of the blood is greatly lessened, then follows a period of greater rapidity in coagulating, and it is in this latter stage that the thrombi are formed.

These experiments are interesting not only as a possible explanation of the cause of some of the autogenous fevers, which will be discussed later, but in view of the present tendency to inject such complex animal solutions as Brown-Séquard's elixir and Koch's lymph subcutaneously, and they will probably cause us to exercise a little more care in this direction.

That certain febrile conditions are autogenous there can be no doubt. These, like other diseases originating within the system, may be due to either of the following causes: 1. There may be an excessive formation of poisonous substances in the body. Thus, Bouchard has shown that the urine excreted during the hours of activity is much more poisonous than that excreted during the hours of rest. Both physical and mental labor are accompanied by the formation of these deleterious bodies, and if the hours of labor are prolonged and those of rest shortened, there will be an accumulation of effete matters within the system. 2. The accumulation of the poisonous matters may be due to deficient elimination. 3. Some organ whose duty it is to change harmful into harmless bodies may fail to properly perform its functions. Illustrations of diseased conditions arising from these several causes will be given.

First, we may mention fatigue fever, which is by no means uncommon, and from which the over-worked physician not infrequently suffers. One works night and day for some time; elimination seems to proceed normally; but after a few days there is an elevation of temperature of from one to three degrees, the appetite is impaired, and then if the opportunity for rest is at hand sound and restful sleep is impossible. The tired man retires to his bed expecting to fall asleep immediately, but he tosses from side to side all night, or his sleep is fitful and unrefreshing. The brain is excited and refuses to be at rest. The senses are alert and all efforts to sink them in repose are unavailing. Fatigue fever is frequently observed in armies upon forced marches, especially if the troops are young and unaccustomed to service. Mosso has studied this fever in the Italian army. He states that in fatigue the blood is subjected to a process of de-

composition brought about by the infiltration into it from the tissues of poisonous substances, which when injected into the circulation of healthy animals, induce malaise and all the signs of excessive exhaustion. It is possible that in this decomposition of the blood the fibrin-ferment, which according to Schmidt, is held in combination in the colorless corpuscles, is liberated; and it has been shown by Edelberg, that the injection of small quantities of free fibrin-ferment into the blood causes fever, while the injection of larger quantities is followed by the formation of thrombi, as has been demonstrated by the experiments of Edelberg, Bonne, Birk and Köhlar.

Fatigue fever is often accompanied, especially during the period of elevation, by chilly sensations, and consequently it is pronounced malarial and quinine is administered, but it does no good, often harm by increasing cerebral excitement. The proper treatment is prolonged rest with proper attention to elimination.

Then there is the fever of exhaustion, which differs from fatigue fever only in degree. It is brought on by prolonged exertion without sufficient rest and often without sufficient food. The healthy balance between the formation and elimination of effete matter is disturbed, and it may be weeks before it is reëstablished; indeed, it may never be regained, for some of those cases terminate fatally. The fever of exhaustion may take on the typhus form, delirium may appear, muscular control of the bowels may be lost and death may result.

That the fever of exhaustion has been mistaken for typhoid by some of the ablest clinical teachers is shown by Peter in the following quotation: "It was in 1852," says he, "when entering upon my clinical studies, and ardent in my attendance at the clinic of Chomel, I was witness of the following instance: A young man was received under the celebrated professor's charge, suffering from prostration, muscular pain and rachialgia. Chomel made the examination with all the care and attention used by him, then, as was also usual with him, in the presence of the patient, he gave the diagnosis in Latin, which was *aut febris ptyeicia aut variola incipientis*, either typhoid fever, or incipient small-pox. I felt rather dissatisfied at a diagnosis so little precise, by one so eminent in his art. The truth of the matter was, though Chomel was not aware of it, this young fellow in a state of destitution had walked from Compiegne to Paris, sleeping by the wayside at night and nourishing himself with such refuse food as chance supplied. It was under such circumstances the patient had developed febrile symptoms. The day after his admission and simply from rest in bed, he felt better, and the day following he was altogether well."

That all cases of the fever of exhaustion do not terminate so rapidly as that instanced above

by the great French teacher, is shown by one which I happen to have under my care at the present moment. A lady, rather frail in body, but without any organic disease, spent the greater part of the time day and night for ten days in the sick-room of her child who died with diphtheria. Since the death of the child, the mother has been confined to her bed with a fever which varies from 99° to 102.5° . She has no soreness of throat or other evidences of infection with diphtheria. She has no symptoms of typhoid fever, and with the exception of slight constipation, which has been easily relieved, her bowels have remained in good condition. She took but little food during the sickness of the child and has had no desire for food since. Her temperature is but slightly affected by two-grain doses of antifebrin and the highest point reached each day is very variable. The mind is clear and she has been altogether free from headache. Her temperature is lowered by a few hours sleep. This condition has now continued for nineteen days. I have pronounced this a case of fever from exhaustion, and if this diagnosis is not correct, I must admit that I do not understand the nature of the case.

A case, similar to the above, I saw some time ago in a young man who had been leading quite an inactive life as a student, and who did a very foolish thing in walking one day a distance of more than thirty miles. The next morning he had a fever, which varied from 99° to 103° , and which continued for more than one month. The physician in charge pronounced this a case of typhoid, but of the correctness of his diagnosis there was not the slightest evidence. In this instance, quinine was first employed, but it increased the wakefulness and restlessness, and was followed by an elevation in the temperature.

I have known at least one case of this kind to terminate fatally, and a most thorough post-mortem examination failed to reveal any definite lesion.

Then, again, there is the fever of non elimination, which all physicians of experience have observed. There is a feeling of languor, the head aches, the tongue is coated, the breath offensive, and the bowels constipated. The physician fears typhoid fever, but finds that a good, brisk cathartic dissipates all unpleasant symptoms, and the temperature falls to the normal. This fever is also liable to appear among those who are confined to bed from other causes. Brunton says: "No one who has watched cases of acute diseases, such as pneumonia, can have failed to see how a rise of temperature sometimes coincides with the occurrence of constipation, and is removed by opening the bowels." The surgeon and obstetrician have often had cause to rejoice when they have found a fever, which they feared indicated septicæmia, disappearing after free purgation.

Bouchard has shown that normal feces contain a highly poisonous substance, which may be separated from them by dialysis, and which, when administered to rabbits, produces violent convulsions. He estimates that the amount of poisonous alkaloids formed in the intestines of a healthy man each twenty-four hours, would be quite sufficient to kill, if it was all absorbed. He proposes the term *stercoræmia* for that condition which results from arrest of excretion from the intestine.

It is more than probable that the poisons of the intestines are due to the bacteria which are normally present; but this would not exclude the fever of non-elimination from the list of autogenous diseases. The bacterial cells which are normally present in the intestines, cannot be regarded as invaders from without.

It would seem from some recent studies, that not all surgical fevers are due to bacterial activity. The absorption of aseptic blood clots, and of disintegrated tissue in cases of complicated fractures and contusions of the joints, is accompanied by an elevation of the temperature above normal. A like result may follow the intravenous injection of a sterile solution of hæmoglobin, or of the blood or another animal. The causative agent in the production of these fevers remains unknown. In the blood of twelve out of fifteen patients with aseptic fever, at the clinic of Nothnagel, Hammerschlag has found free fibrin-ferment, but in five persons without fever he found the same substance in the blood. This leaves the causative agent in the production of the aseptic, or more properly speaking, the non-bacterial, fevers unknown.

The chemical theory of so-called uræmia has received support in recent researches, notwithstanding the fact that the old idea that urea is the active poison, and the theory of Frerichs, that ammonium carbonate is the active agent, have been abandoned. Landois laid bare the surface of the brain in dogs and rabbits, and sprinkled the motor area with kreatin, kreatinin and other constituents of the urine.

Urea, ammonium carbonate, sodium chloride and potassium chloride had but slight effect, but kreatin, kreatinin and acid sodium phosphate caused clonic convulsions on the opposite side of the body, which later became bilateral. The convulsions continued at intervals for from two to three days, when growing gradually weaker, they disappeared. Landois concludes that chorea gravidarum is a forerunner of eclampsia. These experiments have been confirmed by Leubuscher and Zeichen.

Falk injected into both sound and nephrotomized animals fresh urine, urine and the ferment of Musculus and Lea, and urine which had undergone spontaneous decomposition, without producing any symptoms which were comparable

with those observed in uræmia. However, he did find that if a few drops of an infusion of putrid flesh was added to the urine before injection, all the typical symptoms of uræmia were induced. That the infusion of putrid flesh alone had no effect, was also demonstrated. This would lead us to believe that some ferment in the infusion converts some constituent of the urine into a highly poisonous body. In this connection, attention may be called to the fact that kreatin may be converted, by the action of certain germs, into methyl-guanidin, which produces convulsions. Whether such conversion occurs in uræmia or not, and if it does what the cause of it is, are questions which must be left for future investigations to decide. It would be well for some one to test the brain and blood of a person who has died in uræmic convulsions for methyl-guanidin.

MEDICAL PROGRESS.

Therapeutics and Pharmacology.

SIMPLE METHOD FOR CONTROLLING EPISTAXIS.—DR. W. W. PARKER, of Richmond, Va., says in the *New York Medical Record*: "The plan of arresting hæmorrhage from the nose, which I here describe, I have used for thirty years without one failure. When I first began to practice I used Bellocq's instrument, but found it painful, and in small children, exceedingly troublesome of application. The little device which I use is made of fifteen of the long threads of patent lint, size three and one-half, or four inches long, which I double on themselves and tie in the middle, and let one end of the string be six or eight inches long so as to pull the plug out when necessary. When doubled on itself it looks like a "comet" in miniature, with a nucleus and thirty tails or twice the number of threads used. A probe is pressed up against the centre, and is passed back upon the floor of the nasal cavity and pushed on till you reach the posterior nares. This will be known both by the resistance and the length of the probe, or the depth which you have reached. Then slowly withdraw the probe and plug the anterior nares and you have arrested the bleeding. These twenty or thirty ends floating in the blood at once coagulate it. The passage of the soft lint gives no pain whatever. If lint is not at hand I use the largest size spool cotton. The plug is removed in from twenty-four to forty-eight hours. It gives no pain and the patient is willing for it to remain. The other methods are all painful in execution, and the discomfort, while the plug remains, is very considerable.

Medicine.

BROMISM AND INTESTINAL ANTISEPSIS.—In a note read before the Société de Biologie, at the

meeting held January 24, 1891, DR. FERRET continues the study of the influence of intestinal antiseptics on bromism, already referred to in a previous number of the *Gazette (La Médecine Moderne, February 5, 1891)*. He confirms the statement already mentioned that not only may one with sufficient doses of naphthol and salicylate of bismuth prevent cutaneous manifestations of bromism, but one may by these means even cure an eruption, if already so produced. He also maintains that borax also may produce eruptions quite as serious as those which follow the administration of large amounts of bromides, and that such eruptions may be likewise treated and cured by the same method. He believes that his experience has demonstrated that this method should be generally employed, and always with a prospect of success in the treatment of the cutaneous manifestations which follow the ingestion of drugs — *Therapeutic Gazette*.

CHRONIC RHEUMATISM AND THE NERVOUS SYSTEM.—A novel and suggestive, if somewhat revolutionary, theory in reference to the dependence of chronic rheumatic joint changes on a morbid condition of the central nervous system is advocated in a work by DR. WICHMANN, of which an abstract is furnished in a recent number of the *Centralblatt für Klinische Medizin*. The author began his work six years ago, with the view of explaining the nervous symptoms associated with rheumatic joint affection, and the dependence of those upon a central cause was first suggested by the occurrence of symmetrical phenomena such as patches of erythema, subcutaneous nodules, etc. Charcot has explained the occurrence of contractures in rheumatism by supposing that there is an inflammation of the articular nerves, the influence of which is transmitted to the centres in the cord, there giving rise to irritation of the motor roots: and the fact that the contracture is usually in the flexed position is explained by the greater power of flexors as contrasted with extensors. But it is pointed out that this would not explain the occasional occurrence of extensor contraction, and that, moreover, in other conditions giving rise to joint affection, such contractures do not take place. Further, as supporting the theory of a central lesion for those conditions, attention is directed to the occurrence of arthropathies in tabes and other spinal conditions, and it is contended that a feasible explanation of the vaso-motor and trophic disturbances—such as "glossy skin"—as well as of the disturbance of sensibility, is offered by such a hypothesis. — *The Lancet*.

CHLOROSIS AND ITS TREATMENT.—DR. FREDERICK SCHOLZ, of Bremen, has published a remarkable work on chlorosis, the outcome of observations made during the last twenty years.

Instead of regarding the deficiency of iron or hæmoglobin, or even that of the red corpuscles, as the primary affection, he states that contraction of the vessels is always present in these cases, as indeed was observed by Bamberger, Rokitsky and Virchow; and this, he contends, is not to be regarded as a complication due to an altered condition of the blood, but as the primary condition which is followed by the morbid change in the blood. As a matter of fact, the vessels are, he says, too full, or in the condition termed by the older physicians *plethora ad vasa*, the blood being—or becoming—abnormally serous. Long ago his attention was struck by the cold and livid condition of the skin in anæmic subjects, and he was led by this to employ hot baths, together with gentle friction, in the treatment, with the view of acting directly upon the skin, so as to improve the vitality and nutrition generally. The success of his first attempts was so marked that he was encouraged to persevere in this line of treatment, and he has since had many opportunities of extending his experience with it. Hot baths diminish the plethora by relaxing the tension of the vascular system, which is high, quickening the circulation, and thus relieving the palpitation, dyspnoea and other symptoms. In thirty cases where the distress of the patient was very great, Dr. Scholz has gone a step further and supplemented the hot bath by venesection. Paradoxical as this treatment may appear, it was followed by marked benefit, and if the theory of the pathology of chlorosis above mentioned be correct, there can be little doubt that the novel line of treatment practiced by Dr. Scholz is justifiable.—*Therapeutic Gazette*

Surgery.

THE TREATMENT OF STRICTURE OF THE MALE URETHRA.—DR. J. WILLIAM WHITE (*University Medical Magazine*, Vol. iii, No. 6, 1891), after giving his views *in extenso* as to the treatment of organic stricture of the male urethra, summarizes them as follows:

1. Strictures of large calibre—that is, of more than No. 15 French, situated at or behind the bulbo-membranous urethra—are to be treated, almost without exception, by gradual dilatation.

2. Strictures of large calibre, occupying the pendulous urethra, are to be treated by gradual dilatation when very recent and soft, and by internal urethrotomy when of longer standing, distinctly fibrous in character, or non dilatable. It is to be remembered that the great majority of so-called strictures of large calibre of the pendulous urethra are merely points of physiological narrowing.

3. Strictures of the meatus and of the neighborhood of the fossa navicularis should be divided upon the floor of the urethra whenever it is evident that they are real pathological conditions

producing definite symptoms, and not normal points of narrowing.

4. Strictures of small calibre (less than No. 15 French) situated in advance of the bulbo-membranous junction, unless seen very early and found to be not usually soft and dilatable, furnish the typical condition for internal urethrotomy, which should be done preferably with a dilating urethrotome, and invariably with all possible antiseptic precautions.

5. Strictures of small calibre (less than No. 15 French) situated at or deeper than the bulbo-membranous junction should be treated, whenever possible, by gradual dilatation. In a case of resilient irritable or traumatic stricture in this region, or of stricture, which, for any reason as the occurrence of rigors, is non dilatable, external perineal urethrotomy is the operation of choice.

6. Strictures of the deep urethra permeable only to filiform bougies should be treated by gradual dilatation when possible, the filiform being left *in situ* for some time, and followed by the introduction of others, or used as a guide for a tunnelled catheter. If the stricture be not suitable for dilatation, external perineal urethrotomy should be performed.

7. Impassable strictures of the deep urethra always require the performance of perineal section.—*American Jour. Med. Sciences*.

WHAT BECAME OF A SOFT RUBBER PESSARY.—According to a report of the St. Louis Medical Society (*Chn. Lect. Clinico* Dr. W. B. DORSETT exhibited fragments of a soft rubber ring or air pessary, with the following history: Patient over 50, admitted to hospital for supposed cancer of uterus. She had fever, a very offensive discharge from the vagina, and much pain. The use of a syringe revealed a hardened pessary, which required to be broken into pieces before removal. The pessary had been introduced one month before, but had become hard and inflexible by the action of the vaginal secretions, causing indirectly excoriations, fissures and lacerations, with septicæmia as the result. Dr. Jacobsen followed with the statement that he had removed a pessary reposit about five months before, and which had been closed over by the vaginal walls. A very offensive discharge was also present in his case.

Pathology.

ETIOLOGY OF TETANUS.—Tetanus, as distinguished from the tetanic spasms of strychnine poisoning, and the opisthotonos, etc., incident to some myelites, has generally been considered as a disease, or aggregate of phenomena, consisting essentially of a tonic spasm of all the muscles of the body, beginning with those of the jaws and neck, and ending with those of respiration. Two

forms have been recognized—the traumatic and the idiopathic; the former always following the reception of some wound, either one into which dirt has entered, or which has taken on an unhealthy character; the other, in which no such cause has been discovered, has been attributed to exposure to cold and wet—such an explanation being, however, based on negative evidence.

But the researches of Carle and Rattone, Nicolaier, Rosenbach, Brieger, Beumer, Langer and Eiselsberg, leave no room for doubt that it is properly to be classed among specific diseases, and that the phenomena are caused by the entrance into the organism of a microbe which exists outside of the body, and is widely or almost universally distributed in earth and dust. It has been induced in animals by the injection of emulsions of, or the juice expressed from, the sciatic nerve of men or other animals that have died of the disease. Nicolaier used common garden soil with success, though the same earth, when baked or otherwise sterilized, merely set up local irritation and abscesses. Rosenberg discovered and used a bacillus present in the substance of the nerves of tetanic individuals; Brieger employed a chemical product derived from pure cultures of the bacillus; Beumer used all these means; and Eiselsberg has recently reinvestigated the whole question.

The first impulse to research in this direction was given by Drs. Carle and Rattone, who, observing an extraordinary proportion of cases of tetanus among a number of workmen admitted to the hospital in consequence of injuries received by the fall of some old buildings in course of demolition, concluded that there must have been some common and local cause, and thought that it was most probably to be found in the dust that had entered the wounds. Inserting some of the dust gathered from the place into the subcutaneous connective tissue of various animals, they produced tetanus in the larger proportion.

Langer reported the cases of five horses who died of tetanus after castration with the same écaraseur, which, having been subsequently boiled in oil, was used without ill results.

Eiselsberg, having verified by experiment the results obtained by all previous observers, comes to the conclusion that the belief in the spontaneous origin of some cases of tetanus, like those of erysipelas, is based on errors of observation, some abrasion being present though unnoticed.

The greater frequency of tetanus after wounds, especially lacerated wounds of the hands and feet, is easily accounted for by the fact that, in the acts of grasping or treading, such wounds are most likely to be attended by the entrance of dirt. —*American Journal Medical Sciences.*

AN EARLY ATAXIC SIGN.—WEISS, of Vienna, says that an early symptom of locomotor ataxia

is an inability on the part of the patient to walk backward, while as yet, and in other ways, he may be able to walk with firmness and rapidity. Perron, of Bordeaux, has also, as we stated several weeks ago, recently suggested an early diagnostic sign, which is simply a modification of the Romberg test—namely, causing the suspected ataxic patient to stand upon one leg, instead of two, with the eyes closed. If the patient shows a tendency to fall, it may be inferred that the spinal trouble has begun which will lead on to locomotor ataxia, even if the Romberg test fails, as it not infrequently does in cases that are not well advanced. —*New York Medical Journal.*

HEMIANOPSIA AS A DIAGNOSTIC SIGN OF BRAIN DISEASE.—At the close of an interesting paper on the above subject the author says:

The following propositions embody the main points, together with a few to which time does not permit me to refer:

1. Lateral homonymous hemianopsia is always the result of a lesion between the chiasm and the occipital lobe, situated on the side opposite to the blind half visual fields.

2. Temporal hemianopsia is invariably the result of a lesion involving the chiasm, and probably always its central mass, though possibly its under surface.

3. Nasal hemianopsia is always the result of arterial disease, or possibly two symmetrical morbid growths, pressing on outer margins of chiasm.

4. Horizontal hemianopsia may be the result of a symmetrical lesion of both occipital lobes, so situated as to involve homologous quadrants of the retina; or possibly a lesion pressing upon the under or upper surfaces of the optic nerves.

5. Color hemianopsia is always of cortical origin.

6. The presence of the pupillary light reflex in the blind segments of the retina, proves that the lesion is back of the basal ganglia.

7. The decussation of the optic fibres in the chiasm is partial, but varies considerably in degree, thus explaining the variations in the size of the blind fields in lateral homonymous hemianopsia.

8. In temporal and nasal hemianopsia, and all other cases of hemianopsia, due to lesion in front of the basal ganglia, all forms of vision are invariably lost.

9. The macula lutea, and a variable space around it, is supplied with fibres from both hemispheres, thus explaining the pretty constant preservation of central vision, as well as variations of the boundary line between the blind and sensitive fibres of the retina in cases of hemianopsia.

10. Choked disc can no longer be regarded, as stated by a recent systematic writer (Ranney), as an absolute contraindication against the trephine. —McCaskey, in *American Lancet*.

Address

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 68 WABASH AVE.,

CHICAGO, ILLINOIS.

All members of the Association should send their Annual *Dues* to the *Treasurer*, Richard J. Dunglison, M.D., Lock Box 1274, Philadelphia, Pa.

LONDON OFFICE, 57 AND 59 LUDGATE HILL.

SATURDAY, MAY 16, 1891.

THE EDITORIAL MANAGEMENT OF "THE
JOURNAL."

The emphatic endorsement of the editorial and business management of THE JOURNAL by the Association in general session, and the recommendation that the same be continued were, of course, matters of extreme satisfaction to those charged with these duties, as was the unanimous concurrence of the Board of Trustees in the decision to continue the publication of THE JOURNAL at Chicago.

A very large number of the members supposed that the continued publication of THE JOURNAL in that city also ensured the continuance of its former editorial and business management. Upon this latter question its Trustees are divided, and not being able to reach a satisfactory conclusion at Washington, a special meeting is called to meet at Chicago for the final decision of the question.

In view of this fact we wish to express our sincere thanks to the profession, and especially to the medical press, for the very cordial consideration which we have received at their hands, and to state that with this number of THE JOURNAL the editorial supervision which has existed for the last two years will terminate.

THE FORTY-SECOND ANNUAL MEETING.

The annual meeting of the Association at Washington convened on May 5. The general sessions were held in Albaugh's Opera House, and the Sections were assigned to various assembly rooms in the city. DR. D. C. PATTERSON, as

Chairman of the Committee of Arrangements, was everywhere present as occasion required, and discharged the duties incident to his position in a manner most admirable.

To the HONORABLE JOHN W. ROSS, one of the Commissioners of the District of Columbia, the Association was indebted for a most cordial welcome. In the course of his Address he proceeded to consider the fact that while there was a sacredness of relation between the client and his counsel barring the latter from the communication of knowledge obtained from the client, no such relation and restriction existed between the physician and his patient. He expressed his surprise that the medical profession had not required at the hands of legislators such exemption from the requirement to divulge professional secrets as obtains with the legal profession. His allusions to the Hippocratic oath were with words well chosen, and the eloquence of his delivery lent a special interest to the opening session.

The President's annual address, delivered by DR. W. T. BRIGGS, of Tennessee, was finely conceived, concisely expressed, delivered in a most creditable manner, and was received by the Association with repeated expressions of applause. He spoke of the desirability of a unification of the entire profession—referring to the organization of this Association, the work it had already accomplished, and paying a feeling tribute of respect to its few surviving founders. His recognition of the rapid advances made in this country in medical education was highly complimentary to our medical colleges, and his anticipations of a still higher standard of requirements for graduation in medicine were most hopeful. He advocated such modifications of present methods as would assure more of science and less of business in our annual meetings. He advocated the development of an additional Section, to be devoted to original research. He spoke at length upon the question of the further development of THE JOURNAL and the necessity, by means of ample remuneration, of securing the best possible representation both of talent and culture in its editorial management.

At the conclusion of his address a committee was appointed to consider its various recommendations, and report upon the same at a suitable time.

The President acquitted himself in a manner

most creditable as a presiding officer. His rulings were prompt, decisive and impartial, and commanded universal satisfaction.

The addresses which were presented in the successive morning sessions were of a high order of merit, as might have been anticipated from the known ability of the men charged with their preparation. But interesting as they were, we cannot refrain from expressing the conviction that more of the morning hours devoted to Section work would materially enhance the value of our annual sessions.

Neither time nor space will permit reference to the special work in the Sections. Our readers are referred to their several reports. The success in several of the Sections, both in the securing of valuable papers and eliciting able discussions of the same, has been beyond previous precedent. In due time their publication will attest the fact.

The receptions and entertainments were in keeping with the well known hospitality of our Capital City. That, given by the physicians of the city, at the Arlington, was largely attended and highly enjoyable. The reception given by DR. W. A. HAMMOND was also largely attended and a most cordial welcome was fully appreciated.

The report of the General Secretary will give the details of the meeting in full.

Detroit will be the next place of meeting under the presidency of DR. HENRY O. MARCY, of Massachusetts.

THE VALUE OF KOCH'S TUBERCULIN.

In *surgical tuberculosis* tuberculin has given more satisfactory results than in pulmonary disease. At any rate, no German surgeon has spoken of it with the want of confidence which marks a few of the reports from clinics for internal disease. In tuberculosis of bones and joints it has proven a valuable remedial adjunct if used with discrimination. Wherever the indications are that a tubercular joint requires operative measures, tuberculin is not a substitute for an operation. But in the early stages, where conservative treatment has a fair chance, the desired recovery can be obtained with much greater certainty and in a much shorter time by the use of tuberculin, in conjunction with rest and the usual means of conservative treatment. This observation, made by many surgeons, proves that in those cases, like the incipi-

ent stages of joint disease, where a spontaneous disappearance of tubercle can occur, the natural mode of repair is powerfully aided by the remedy. On the other hand, it is not unlikely that the very object, the reabsorption of the tubercular infiltration, without destruction of tissue, can be frustrated by too intense reaction. If the destruction has gone too far for conservative treatment, tuberculin alone is of no service. Whether its action can facilitate a subsequent operation by allowing the surgeon to distinguish more easily between healthy and diseased tissue, on account of the partial necrosis of the latter, has not yet been definitely decided. All observers agree that the action of tuberculin shows to best advantage after operations removing the tubercular parts. For now, if no reaction occurs, a definite guarantee of freedom from tubercle bacilli is given, which the most thorough operation does not give with equal certainty. If, however, the parts are still infected, the wounds heal and close with a rapidity which contrasts favorably with the frequent persistence of fistulæ and the not rare necessity for secondary operation after treatment without tuberculin. The published reports seem to show that in surgical cases without internal complication, tuberculin is more manageable in its effect and evidently a less dangerous agent than in phthisis and other internal localizations.

While tuberculin produces a decided local reaction in tuberculous glands, followed by their shrinkage, it does not appear as yet from any report that such glands can be completely cured, at least without operation. Occasionally they suppurate after injection, and can then be opened, healing in this way quite promptly.

The reaction to tuberculin (local as well as general), has proven the tubercular nature of various forms of disease, hitherto not known to be such. Koenigshoefer and Maschke claim to have seen local reaction, with a decided curative tendency, in a form of chronic iritis, as well as in a case of (non syphilitic) interstitial keratitis. Their reports, however, are not complete enough to be convincing. More reliance may be placed in the same authors' statements concerning the curative effects of the lymph in a case of conjunctival disease, closely resembling trachoma. They also found that corneal ulcers in scrofulous children react favorably to tuberculin. The same observation has been made, as to the reaction of cor-

neal infiltration at least, in *some* of the scrofulous cases by Uthof (and also by the writer). Several reports from other hospitals also state that in a few instances, under the tuberculin treatment, an ulcer developed in the cornea, which healed with a promptness suggesting its tubercular nature and the influence of the agent upon it. A very striking instance of tubercular tumor of the uvea is described by Landgraf, which disappeared completely by absorption in consequence of thirty-five injections made in the course of six weeks.

In looking for an explanation of the action of tuberculin it must be remembered that the substance does not directly destroy the bacilli in the tissues. This statement made by KOCH has been corroborated by ISRAEL, SCHIMMELBUSCH and others, by inoculating animals successfully with tubercular material taken from patients under the tuberculin treatment.

As KOCH stated originally, tuberculin acts not upon the bacilli, but upon the tubercular tissue. Coagulation necrosis, which KOCH referred to as the result of the remedy upon the diseased part, has not been found to occur in the human subject except as the result of an excessively intense reaction, and then only occasionally. Patches of skin in lupus and granulations in fungus joints may become necrotic in mass, but this is an exception rather than the rule. In most instances of post-mortem examinations and of specimens taken from the skin of lupus patients under the action of the agent no evidences of necrosis of any of the cells constituting the tubercle have been found. But clinical as well as microscopical observation shows that tuberculin causes an inflammatory process in and around the tubercular part. There is intense congestion and effusion of serum with more or less white corpuscles. The effused serum forms minute vesicles under the epithelium over the lupus nodule, and even detaches the epithelium ultimately. When the transient inflammation has subsided the previous histological condition is apparently restored. The tubercles and the bacilli they harbor are still there. But after repeated inflammatory reactions SCHIMMELBUSCH has found the lupus nodules gradually shrinking. More advanced reparative changes have been found by RINDFLEISCH in tubercular ulcers of the intestines in subjects dying of pulmonary phthisis. Here the characteristic grayish-yellow coating of the ulcers was disap-

pearing or had disappeared, and their surface was livid with healthy-looking granulations which were cicatrizing from the margins. The microscope showed still the presence of the typical cells of the tubercle, the giant and epithelioid cells, but these were changing their shape into that of a spindle, evidently become transformed into connective tissue. RINDFLEISCH interprets the appearances as denoting an immunity of the tissue against the destructive action of the bacilli.

It must not be overlooked that tuberculin exercises an influence upon the entire tubercular organism, as well as a local effect upon the tubercular tissue. The tubercular subject suffers at certain stages of the disease from constitutional symptoms, like the loss of strength, regular and irregular fever and night-sweats, which can only be construed as the result of systemic poisoning by the products of the tubercle bacilli. These symptoms have in many patients been stopped by tuberculin before the tubercular infiltration had disappeared. It must hence be inferred that the remedy either checks the further formation of poisons by the bacilli—a view not supported by any other evidence—or that it renders the body insusceptible to their action. In view of the similar state of facts as proven to be the cause of experimental immunity in tetanus and in the diphtheria, the last explanation has a good deal of probability. Unfortunately we cannot predict in every case that tuberculin will lead to such a result, or that such immunity from poisoning once established will be permanent. It must be left to future researches to decide what special conditions interfere with the specific curative influence which tuberculin can in certain instances exert upon tubercular disease.

THE THERAPEUTICAL VALUE OF SUSPENSION IN DISEASES OF THE SPINAL CORD.

It cannot yet be said that the question of the utility of suspension in treating patients afflicted with posterior spinal sclerosis, as well as some other diseases of the spinal cord, is settled. Conflicting reports are still published regarding the influence the procedure exercises on the spinal cord; some accepting HORSLEY's experiments that showed it was impossible to stretch the cord during life by any manipulation; and during the past year DR. JAMES COGNEY published a paper in

which he reported experiments on the living and dead subject that showed that a total shortening of the spinal cord was obtained in suspension, that in the lumbar region the cord was unaffected or slightly relaxed, in the cervical region the membranes were slightly stretched, and in the dorsal region the cord was shortened; hence suspension caused relaxation, not stretching, and the former possibly acted mechanically by breaking down adhesions and removing impediments to the circulation. This reversal of the generally accepted theory is diametrically opposite to the results of BONUZZI's experiments, in which a body lengthening of two to three centimetres was found to occur in suspension, and by opening the spinal canal a needle placed in the cord was lowered, from eight to twelve millimetres during suspension, the cord was made thinner and more resistant and the cauda equina very tense; the tension of the cerebro spinal fluid was increased and there were venous congestion and increased rapidity of the circulation. These experiments concur in the main with those of MORTSCHUTKOVSKY.

DR. LUMBROSO has experimented with animals, finding a very evident elongation of the vertebral column and the cord, as well as an anæmia with subsequent vascular congestion of the meninges and cord that attained a maximum intensity not at the moment of suspension, but afterward. He advises suspension of short duration as the spinal anæmia observed might be dangerous if protracted; the traction should be graduated by the weight of the patient; and the séance should last for a few seconds in the beginning, gradually being increased to one or two minutes, each séance being followed by an interval of from forty-eight to seventy-two hours. Not only has this treatment benefited ataxic patients, but also patients having infantile paralysis, amyotrophic lateral sclerosis, progressive muscular atrophy, etc.

ALTICHERI reported during the past year one hundred and seventy-four cases of ataxia in which suspension improved the patient in one hundred and twenty-eight cases, produced no result in twenty-six, and in twenty cases the treatment was interrupted. In pseudo-tubercles and impotence he found this treatment very valuable; while in paralysis agitans, disseminated and lateral sclerosis, and chronic myelitis his results were too variable.

GILLES DE LA TOURETTE finds that paralysis agitans in the middle period of the disease, chronic sciatica, and ataxia are benefited by suspension. In the latter diseases one fourth of the cases are greatly improved, thirty-five per cent. are benefited moderately, and forty per cent. are not benefited.

ROSENBAUM obtained in seventy-six cases of ataxia, improvement in twenty-five, doubtful results in nine, no improvement in twenty-seven, and in fifteen cases treatment was interrupted. In four cases of myelitis, three of paralysis agitans, one of disseminated sclerosis, and one of lumbago, no benefit followed this treatment.

BENEDIKT in two and TIERGHIEN in twenty-six cases reported favorable results from suspension.

These figures show that during recent months the therapeutic application of suspension has not lapsed into desuetude, and a more careful study will probably indicate what class of cases will be most benefited by it. Certainly anything that will ameliorate more or less distressing symptoms in sixty per cent. of ataxic cases should not be relegated to the lumber-room of therapeutical appliances.

"CROWNER'S QUEST LAW."

A New York daily has begun to stir up the coroner's office with a long pole, perhaps with no higher aim than to amuse the public with a sensation, but yet some good may result. The charges of inefficiency, ignorance and indifference are somewhat sweeping, and the proposal to delegate the functions of the office to the police rather preposterous. The intimation that autopsies are much to infrequent may be true, but the time was not long ago when a counter-charge was on the popular tongue, and special legislation was invoked for the cutting off of the fees, which resulted in making searching examinations discretionary. Increase of population we cannot but admit has really demanded more work and speedier dispatch in its performance. Besides, too, in communities polyglot in character and of a somewhat feeble public virtue, political plums are expected to grow on every tree. Herein lay the root of the evil.

The office itself is a relic of antiquity and, as the name imports, originally represented the

Crown, its sole function being the detection of crime. Thus from time immemorial a glamour has clung to it like a nimbus and inspired a vague dread of consequences to the extent of the common refusal of cutting down a swinging suicide with the remote probability of saving life. Too much legislation has been wasted in attempting to keep up this office, which should have been left to expire of its own volition. All the errors, according to our idea, belong inherently to the office itself more than to its administration. Certain of the verdicts rendered have partaken of the grotesque and have profited the profession very little,—the officials in the main have been nominated on account of their party zeal and not for their intelligence; their subordinates have been obliged to perform their responsible duties in a perfunctory way, and an easy-going public have fallen upon the conclusion that the dead need no avengers. The remedy lay in the appointment of physicians, probably avouched for by health boards, medical examiners in very truth, such as Massachusetts has set up as models by way of an experiment. The world has become wise enough to intrust the profession with these its proper duties, and so give opportunities for contributions to pathology by all those incumbents who are content to exchange emolument for the ambition of beneficence. When all this is accomplished the verdict "Heart Failure" will take its place alongside of the more pious one of "Visitation of God," and floating corpses will not all have once been animated by inebriates, who have tottered down into the sewer-tainted rivers of those cities whose aspirations are chiefly commercial.

EDITORIAL NOTES.

A DISTANT WITNESS FOR VACCINATION.—Small-pox was carried by a vessel to Ooshooia, near the southern extremity of Terra del Fuego. At that point there is a mission settlement containing about 150 natives, under the care of Mr. E. C. Aspinall, medical superintendent, and five other English ladies and gentlemen. A single case was left by a Buenos Ayres Captain, near Ooshooia, and all the natives were made, in spite of the protest of Mr. Aspinall, to load the vessel with wood for its return to Buenos Ayres. The consequence was an epidemic of not less than

sixteen cases—the disease not being surely spent at the time of the last writing—with nine deaths. The mission church was emptied and converted into a hospital. In order to keep the natives from being exposed to the sick or the dead the white people served them, did the nursing, dug the graves and buried the bodies. Fortunately vaccine was not wanting and it was applied at Ooshooia and adjacent plantations among both the Europeans and their native employés. Notwithstanding the vaccinations some of the natives have taken the varioloid, but all the deaths by small-pox occurred among those natives who had not been so treated, or who had been vaccinated after the infection had taken place.

THE EBBO OF INFLUENZA.—Influenza, with fatal results, is now prevailing throughout Britain. It has not shown itself so much in London as in the outlying districts, yet there is ample time for its extensive prevalence in the metropolis, for it is only in the first stages of its re-manifestation.

GRANTS FOR SCIENTIFIC INVESTIGATIONS.—The British Medical Association announces its readiness to receive applications from its members who desire aid in furthering particular research. This patronage of a great association is no small incentive to the hardy and delving medical mind, and certainly will not be without its honest and far reaching outcome—more noble and more comprehensive than mortal sense has power to appreciate.

THE THERAPEUTIC POVERTY OF FIFTY YEARS AGO.—Dr. John Kent Spender, of Bath, a very pleasing writer on therapeutical subjects, has contributed to the *Practitioner*, London, some reflections on the poverty of the profession fifty years ago, in the matter of drugs, as compared with the embarrassment of riches now-a-days. Diseases were then called "incurable" simply because we had not yet discovered the means of curing them. Our medical poverty, in and about 1840, was such that when "crying sufferers entreated us, we could only confess our impotence to help them. There were whole domains of work in which we seemed no better off than Scott's north-country doctor, who boasted of his 'two simples of calamy and landamy.' And we were chided by that therapeutic nihilism which began in the school of Vienna, and has infected a large number of practitioners in all parts of the

world." Pathology with its microscope, diagnosis with its verifying post-mortem, and a laughing skepticism ruled the courts of medicine, for the secrets of healing had not been disclosed. But now we employ our therapeutic possessions as if we trusted them, and we lean upon the rock of physiological experiment and clinical observation. The doubter and the scorner may be with us still, but they have become reticent and retiring in the face of a constantly strengthening array of therapeutic forces. To Sir Thomas Watson and Dr. Latham the profession is largely indebted for indoctrinating that more humane philosophy that the sick have the rights of being cured by earnestness and faithfulness in the application of remedies.

"INTERNATIONAL CLINICS."—J. B. Lippincott Company will, beginning with April, issue quarterly thereafter a work entitled "International Clinics." This work will comprise the best and most practical clinical lectures on medicine, surgery, gynecology, pediatrics, dermatology, laryngology, ophthalmology and otology, delivered in the leading medical colleges of this country, Great Britain and Canada. These lectures have been reported by competent medical stenographers and thoroughly revised by the professors and lecturers themselves. The object of the work is to furnish the busy practitioner and medical student with the best and most practical clinical instruction in concise form. Each volume will consist of over 350 octavo pages, illustrated with photographic reproductions of important cases.

THE PLACE AND VALUE OF TUBERCULIN.—It is not probable that this question will long remain in the present indefinite condition. Reports covering many hundreds of cases, under different hospital management, and under climatic and general hygienic variations, are being rapidly advanced. The "sum" will show the "substance," and the eager public, as well as the earnest physician, will have the foundation of experimental fact upon which to rest their prayerful hopes and sanguine anticipations.

THE ACTION OF COCAINE ON THE CIRCULATION.—As a result of painstaking study in the direction of ascertaining—experimentally—the exact effects of the drug cocaine upon the circulatory system, Dr. Edward T. Reichert (*Ameri-*

can Lancet) arrives at the following important conclusions: 1. Very much depends upon the individual susceptibility in noting the medicinal effects. 2. Repeated small doses first decrease, then increase, and finally decrease the pulse-rate. 3. The cardio inhibitory centres are always affected. 4. The arterial pressure is always increased, unless after large doses, when temporary decrease may happen. This increased arterial pressure may continue longer than the period of acceleration of the heart beat. This increase is chiefly due to stimulation of the vaso motor centres, to some stimulation of the vessel-walls, and to the increased pulse-rate. These and other noted results show, 5, that cocaine is a decided circulatory stimulant.

MEDICAL ITEMS.

HONORS FOR VIRCHOW.—At the last meeting of the German Congress of Internal Medicine, honorary membership was extended to Virchow on the occasion of his 70th birthday anniversary.

GOETHE AS AN ANATOMIST.—Recent correspondence to the *British Medical Journal* says.—"Professor Bardeleben, of Jena, has found amongst Goethe's unpublished papers in Weimar an essay "On the Comparative Anatomy of the Skull of Mammalia," written throughout in Goethe's own hand. The essay is dated 1794."

RELATIVE FREQUENCY OF GALL-STONE IN THE SEXES.—Dr. Furbinger, in his paper read before the last session of the German Congress of Internal Medicine, analyzed the histories of sixty-four cases of gall-stone treated by him at the Friedrichshain Hospital, and of this number thirteen were males and fifty-one females.

ANOTHER CONSUMPTION CURE.—It is now announced that M. Germain-Sée has developed a method of cure for this great bane. Germain-Sée places his patients for several hours daily in a hermetically closed chamber into which a current of compressed and medicated air is slowly admitted. The air is medicated by passing it through a mixture of creasote and eucalyptol. Results are to appear later.

QUININE BY SYNTHESIS.—Two Frenchmen, MM. Grimaux and Arnaud, announce that they have discovered a synthetical method of preparing quinine.

AMERICAN MEDICAL ASSOCIATION.

Forty-second Annual Meeting, held at
Washington, D. C., May 5-8, 1891.

GENERAL SESSION—FIRST DAY.

The Association assembled May 5 at Allbaugh's Opera House, Washington, D. C., at 10 A.M. It was called to order by Dr. D. C. Patterson, Chairman of the Committee of Arrangements; who introduced Rev. S. M. Newman, D.D., of the First Congregational Church, who offered a prayer. The Hon. John W. Ross, Commissioner of the District of Columbia, welcomed the Association to Washington. The Chairman of the Committee of Arrangements, announced the programme and other arrangements for the meetings.

The President, Dr. William T. Briggs, Tenn., took the Chair, supported by Vice-President Dr. C. A. Lindsley, Conn., and ex Presidents Drs. T. G. Richardson, W. W. Dawson and P. O. Hooper. The President then delivered the

ANNUAL ADDRESS.

(See page 649.)

On motion of Dr. J. C. Culbertson, O., thanks were tendered the President for his able address, and a committee of five was appointed to develop the points therein, and to report to the Association the last day of the meeting. Committee—Drs. Culbertson, Hooper, Moyer, Marcy and Connor.

Dr. Hooper, of the Board of Trustees, presented a preliminary report from that body.

To the President and Members of the American Medical Association:

The Board of Trustees have the honor to make a preliminary report on the question of location of THE JOURNAL.

At a special meeting of the Board, held in November, 1890, the Trustees, having individual views as to the best method of strengthening THE JOURNAL, resolved to recommend, first, an established home; second, that that place of permanent establishment be the National Capital. After free discussion and interchange of views, it was resolved to submit the question to the members of the Association, through the columns of THE JOURNAL, before making their final report. The result of that course of action has been to convince them that the majority of the members desire that the place of publication shall continue to be in Chicago. They, therefore, in obedience to that expressed opinion, hereby report that Chicago is the undoubted choice of the Association as the place of publication of THE JOURNAL.

The undue excitement that has taken place in regard to the matter, and the sectional antagonism that has been engendered, is to be deprec-

ated, but the controversy has strengthened THE JOURNAL by increasing the subscribers, and stimulating the interest of members heretofore lukewarm, and they make this preliminary report in order to promote harmony in the meeting, quiet misapprehension, and give due notice of this action in advance of the regular report.

P. O. HOOPER, Pres't.

JOHN B. HAMILTON, Sec'y.

On motion, the report was received with thanks, and unanimously adopted.

The amendment offered by Dr. A. L. Gibson, U. S. Navy, at the last meeting, was then taken up. "To amend the By Laws so as to make the General Sessions commence on Wednesday, in place of Tuesday."

A motion by Dr. N. C. Scott, Ohio, to lay the amendment on the table, was lost.

On motion of Dr. I. N. Quimby, N. J., the subject was laid over until 11.30 A.M. on Wednesday.

Dr. Barrington, of Ireland, was, on motion of Dr. R. Reyburn, D. C., made a member by invitation.

Dr. N. S. Davis, Ill., announced that the American Medical Temperance Association would meet at G. A. R. Hall on Thursday, at 9 A.M., and invited all to join the Association.

Dr. Gibson then read the report of the Rush Monument Fund.

REPORT OF RUSH MONUMENT COMMITTEE.

For the seventh time, after as many years, the Rush Monument Committee are only able to report *progress*, but progress so slow that seven times seven years, at this rate, will find the end still unattained which, seven years ago, seemed to be a matter of only as many months.

Those of you who were present at the Washington meeting in May, 1884, when the idea of this monument was broached, will remember with what alacrity the proposition was received. The large body of delegates and members in attendance, at that meeting, were struck, as you cannot fail to be, when you visit the manifold attractions of this beautiful Capital, by the fact that, in this city of monumental memorials of the distinguished Fathers of the Republic, there is not one of any medical man. Is this, repeating language heretofore used, because among the patriotic builders of this nation, our profession has not furnished one? Are painters and sculptors, presidents and judges, generals and admirals, scientists and discoverers, teachers and divines, philanthropists and politicians only those who have deserved this recognition from their country? Has there been no great doctor in medicine whose life has been as exemplary, whose patriotism as exalted, whose fame as extended as any of these men whose marble effigies confront us in whatever direction we look in this sanctuary centre of our

great country? Or is it that Medicine, alone among the professions, fails to honor its own sons and give them royal acclaim for royal deeds?

During the seven years in which your Committee have been employed upon the unwelcome task of soliciting contributions for this monument, which this Association has year after year commended with enthusiasm, two facts have become patent; *first*, that the events of our National history of which the achievements of American physicians were important parts, are not made matters of medical education, else the name of Benjamin Rush would be a household word in every doctor's dwelling in the country; and *second*, that in the city which he honored with his residence, life-work and heroic sacrifice unto death, petty animosities and jealous rivalries have survived, in the descendants of men of lesser light and lesser renown, to harden their hearts and tighten their purse-strings, in refusing to honor the name and perpetuate the memory of one whom great physicians of this day declare to have been the greatest physician, patriot, philosopher and philanthropist, all in one, which this country has ever produced.

Disheartened at the slow increase of the Rush Monument Fund, especially when statues of later inception were being completed to men of other callings in this country, for labors that were not distinctively National, and to physicians, in foreign lands, whose services to humanity were far less valuable, your Committee sought advice as to better or more practical methods of operation. One suggested by an eminent promoter of charitable enterprises seemed to them worthy of trial—the distribution of "coin cards," or cards containing a space in which a silver half dollar could be placed by the contributor. To spare them all trouble whatsoever, a stamped envelope, printed with the Treasurer's address, was printed, that he might have nothing more to do than place a half-dollar in the space in the card, inclose that in the envelope, seal and drop it in the nearest mail box.

Your Committee deemed it expedient to begin the distribution of these cards in Philadelphia, with which the name of Rush is identified, in the hope that there where his active life was passed, and where a local memorial—the Rush Library, recalls his prominence in medical literature, there would be such generous response to your Committee's application, that they could go to other cities and places, with these first fruits, as earnest of what might be done everywhere.

Accordingly, the following letter was addressed in my own hand to 1,770 individuals in the city of Philadelphia:

Dear Doctor:—I beg to make, hereby, a final appeal to you, as a member of the medical profession in the city of Philadelphia, to contribute in behalf of the monument to be erected at the National Capital to the renowned patriot, Dr. Benjamin Rush, whom one of your

distinguished colleagues declares to have been "the greatest physician this country has ever produced."

The liberality with which Philadelphians contribute to this memorial of one of the greatest men to whom their city has ever given birth, will be evidence to other sections of the country of the esteem in which he is held by the people of his own home. I, therefore, most earnestly solicit you to inclose whatever you may feel disposed to give, whether check, banknote, or only a half dollar coin to be placed in the space in the card, in the within envelope, mailing it by return post as addressed. Should you have already contributed all you intend, or should you conclude to give nothing, will you kindly oblige the Committee by remailing the envelope, with enclosed card, that the latter may be used elsewhere? Very respectfully, for the Committee,

ALBERT L. GHON, Chairman.

But notwithstanding the request, "should you have already contributed all you intend, or should you conclude to give nothing, will you still kindly oblige the Committee by remailing the envelope, with inclosed card, that the latter may be used elsewhere?" and the fact that a stamped two cent envelope, bearing the Treasurer's printed address, was inclosed for the purpose, more than 1,600 were never returned. About 160 responded, making, with the 40 Philadelphians who had previously contributed, about 200 in all, or only 11 per centum of our profession in that city, who have exhibited any interest in this work. The cost of circular letter, cards, envelopes, stamps and folding, was \$95, the sum received \$150, a net gain of about \$55, a not very encouraging yield from so wide a field of operation as this million peopled city. Being a Philadelphian, the Chairman of your Committee was absolutely sure that we would get the half-dollar from at least 1,500 of the physicians addressed, but we have actually had only two responses from the doctors, who rejoice in *feminine* Christian names, who we were positive would outdo their brother mediceos in liberality, as they do in all the other virtues.

In the light of this experiment, what then is to be done? Abandon the undertaking? Never! The fund already accumulated is a sacred trust, which can be diverted to no other purpose. There is no reason to apprehend that Congress will be less liberal than it has been to other projects of this kind; and if it donate a pedestal appropriate for such a statue as the medical profession of 106,000 members ought to erect, who will care to see a \$2,000 statue surmounting a pedestal costing \$25,000 as that of the McPherson statue did, or \$30,000 like that of the Garfield Monument?

The seed has been planted, and if properly cared for, it is bound to grow, and except you be dissatisfied with our tillings of the soil, we shall persevere through this and many summers more. It was forty-three years from its inception before the beautiful shaft of the Monument to Washington graced the twilight sky of the Potomac's banks, and though some of us can not hope to live until forty-three years shall have passed to

see the noble features of this great physician, whose name one need not hesitate to utter where that of Washington rings, upon the generation, which shall then visit the Army Medical Library and Museum, and find his effigy its greatest ornament; still while we may live, we pledge ourselves to labor to this end, so long as this Association shall honor us with its stewardship, aspiring to no other reward than to have succeeded in rearing in imperishable bronze or enduring stone, the figure of this great man, the model physician, the worthy citizen, the brave patriot, the gallant officer and broad-minded philanthropist, whom it is every American medical man's duty to reverently honor.

Why should Americans alone among the physicians of the world be indifferent to the glorifying of their illustrious dead? The Italians have within three years, erected at Milan, their monument to their patriot physician, Agostino Bertani, a splendid bronze statue by their great artist Vela, besides placing a marble tablet on the facade of his home in Genoa. The recent Congress of Russian medical men at Moscow determined, with great enthusiasm, to erect a monument as a national memorial to Nicolai Ivanecoitsh Pirogow, the Thinker-Surgeon, whose 71 years ended only ten years ago. A Committee of French physicians has just been organized, with Professor Fourmier as its President, to do, as we have been so long striving, raise a monument to Philippe Ricord, and subscriptions are reported to be coming in spontaneously and rapidly. At Giessen in Ober Hesse, the scene of his famous labors, on the 23d of last July, a white marble statue was erected to Liebig, larger than life size and ornamented with figures, emblematic of science and culture, and another is projected at Halle, in Saxon Prussia, to Professor Richard von Volkmann, for which subscriptions are being gathered in America, and to which one American Association was on the point of contributing when a member pertinently suggested that at least an equal sum be contributed to the Rush Monument—so neither got any. A few days ago, the papers announced "contributions have been made already in and about Boston alone, by the following physicians," mentioning twenty names, aggregating \$245.00 for the *Virchow* Testimonial Fund. German physicians also liberally contributed to the life-size monument in bronze to the late Emperor Frederick II, erected in the quadrangle of the Protestant Hospital at Kaiserslautern.

Why should physicians alone in this country object to do public honor to their conspicuously great men in their profession? The New York Academy of Sciences projects a monument to Audubon, and eleven members at once subscribe \$100 each, and in a time, incredibly brief by comparison, \$2,733.50 are collected. The Print-

ers' Union is raising funds for a second colossal statue to Greeley, the first by Ward having long adorned the entrance to the Tribune Building in New York. Deaf mutes planned and executed their monument to Gallaudet standing on Kendal Green, where you all will doubtless see it, and this since we have been talking about our statue. The members of the legal profession have their \$40,000 monument to Chief Justice Marshall at the approach to the Capitol, and Story's classic figure of Professor Henry stands near Smithsonian Institution as ours of Rush should stand near the National Medical Library and Museum. A few Brooklyn Protestants have built a monument to Beecher and in one night \$1,700 were subscribed by Roman Catholics in New York City alone for the bronze statue of Archbishop Hughes at Fordham, \$20,000 being promised before the end of June.

But the list would be a long one were we to enumerate all the monuments that are proposed in this country. Your Committee have not advocated a monument to Rush as in rivalry to any other man. The monument is not to Rush the preëminent individual, as to Rush, the symbol of medical patriotism—the visible expression of the fact that the profession of medicine has contributed its great man—are of its great men if you please—clothed in his professional garb, to uphold the standard of freedom in the foremost rank of the brave defenders of this new nation, and keep it there through all the strife of the Revolution. This Rush did, and later became one of the framers of that venerated instrument, on which the fabric of our nationality is built, the Federal Constitution. For this, he has been chosen to have a place among the sculptured heroes of that time, by whose silent presence, as by their fearless speech when living, they may illustrate to posterity what the purest patriotism and public spirit mean.

Your Committee appeal not for money only, but for collaborators—for volunteer associates, who will act with them as fellow Committee men, each in his own town, and by earnest personal effort aid them in their uphill work. The Association has already given them authority to add to their numbers, and your Committee now ask such of you as care to do this labor of love to give your names and addresses to their Secretary, Professor Rohé, with the assurance of your active cooperation. The Washington Monument was mired eleven years. The Rush Monument is making scarcely greater progress, but with your willing shoulders to the wheel, it will, in good time, soon make triumphant advance.

ALBERT L. GIBON,
Medical Director U. S. Navy, Chairman Rush Monument Committee.

On motion of Dr. H. D. Holton, Vermont, the report was received and the Committee continued.

The Permanent Secretary read the report of the Treasurer:

TREASURER'S REPORT.

The treasurer has the honor to report that the balance in the treasury of the Association is \$9,427.21. The statement of the account will be published as usual in the columns of THE JOURNAL of the Association. All of which is respectfully submitted.

RICH'D. J. DUNGLISON, Treasurer.

May 5, 1891.

On motion it was received and adopted.

Dr. L. D. Bulkley, New York, as Chairman of Section on Dermatology, etc., explained why no papers were on the programme for that Section, and moved that said Section be dispensed with.

As this would have required an amendment to the By-laws it was laid over. (Subsequently Dr. B. announced a meeting on Wednesday and the offer of sundry papers for that Section.)

On motion of Dr. C. G. Comegys, Ohio, it was

Resolved, That a committee of three be appointed by the President to consider the question of petitioning the next Congress to create a cabinet officer to be known as the Secretary of Public Health. The report of this committee to be presented on Thursday morning.

Committee—Drs. Comegys, N. S. Davis and T. G. Richardson.

On motion of Dr. L. Connor, Mich., it was

Resolved, That each Section at this meeting be requested to appoint a committee of three which shall meet at the Arlington, May 6, at 9 A.M., to consult as to the best measures for promoting the interests of the Sections, and the best means for securing the adoption of the same.

On motion of Dr. Dudley S. Reynolds, Ky., it was

Resolved, that the Supervising Editor of THE JOURNAL be instructed to secure stenographic reports of the proceedings of each of the several Sections of this Association, and that the Trustees be instructed to set apart a sufficient sum, not exceeding one thousand dollars, annually for that purpose. This resolution to take effect at and after the present session.

On motion of Dr. Chas. A. L. Reed, Ohio, it was

Resolved, That the American Medical Association hereby extends a cordial invitation to the medical profession of the Western Hemisphere to assemble in the United States in a Continental American Medical Congress.

Resolved, That the Committee on Nominations be and is hereby instructed to nominate one member for each State and territory, and one each for the Army, Navy, and Marine-Hospital Service, who shall constitute a committee which is hereby instructed to effect a permanent organization of the proposed Continental American Medical Congress and to determine the time and place at which the same shall be held.

Resolved, That the Committee on Nominations be and is hereby further instructed to report the nominations pursuant to the foregoing resolution at the general session on Thursday morning.

On motion a recess was taken to allow the States to assemble and select their members for the Nominating Committee.

Ala., J. C. Lagrange; Ark., J. M. Keller; Cal., Simmons; Conn., C. A. Lindsley; D. C., G. W. Cooke; Del., Wm. Marshall; Fla., W. E. Anderson; Ga., W. F. McRae; Ill., G. W. Webster; Ind., A. M. Owen; Iowa, G. F. Jenkins; Ky., W. H. Wathen; La., T. G. Richardson; Mass., A. P. Clark; Md., T. S. Latimer; Mich., H. O. Walker; Minn.,—; Miss., B. A. Duncan; Mo., I. N. Love; N. C., J. O'Hagan; N. H., Irving A. Watson; N. J., B. A. Watson; N. Y., John Cronyn; Neb., J. O. Carter; Ohio, C. A. L. Reed; Pa., E. Jackson; S. C., T. J. McKie; S. Dak., W. M. Kaul; Tenn., G. C. Savage; Tex., J. W. Carhart; Vt., D. C. Hawley; Va., W. L. Robinson; W. Va., G. A. Aschman; Wis., J. B. Whiting; U. S. Army,—; U. S. Navy, J. M. Flint; U. S. Marine-Hospital Service., J. B. Hamilton.

After some discussion on motion of Dr. Hamilton the committee was requested to meet at the Arlington at 7 this evening.

SECOND DAY, MAY 6.

The Association assembled at 10 A.M., President Briggs in the chair.

Prayer was offered by Rev. Father Richards, of Georgetown University.

The Chairman announced certain additional arrangements and invitations.

Dr. E. L. Shurly, Mich., read the *Address on Medicine* (see page 721).

The Librarian read his report, which was received and the appended suggestion adopted.

The amendment of Dr. Gihon being in order he again addressed the Association. After much discussion by Drs. Quimby, Scott, Davis, Vaughan, Bishop and Ross, on motion of Dr. J. H. Murphy, Minn., the amendment was finally laid upon the table.

The amendment offered by Dr. X. C. Scott, Ohio, to abolish the Committee on State Medicine, inasmuch as the work was done by the Section on State Medicine, was taken up.

Dr. A. N. Bell, N. Y., moved to amend by saying that this Section should nominate to the Association the persons to constitute the committee. Dr. N. S. Davis, Ill., offered an amendment which was accepted by Dr. Bell, that the nomination be changed in the laws from the Nominating Committee to the Section on State Medicine. This was unanimously adopted.

The amendment offered by Dr. E. A. Wood, Pa., to "omit the word Physiology from the title of the Section on Practice of Medicine, etc.," and form a new Section on Physiology and Dietetics, was almost unanimously adopted.

The amendment offered by Dr. J. C. Culbertson, Ohio, being up, Dr. R. Harvey Reed, Ohio, offered to amend by substitute, when Dr. N. S. Davis, Ill., offered the following:

Resolved, That the proposed amendments concerning the recognition of State and other medical societies as

to members, and the remainder to subscribers, advertisers, exchanges, etc.

The cost of publication and editorial expenses for the year has been \$23 337.97. The receipts at the office from all sources amount to \$14,464.59. Amount drawn from treasury of the Association, \$8,909.38, leaving a balance in the hands of the Board \$762.40. At the same time there was in the hands of the Association Treasurer, \$4503.39. Making a total, March 31, 1891, available, of \$5,265.79. Full detailed exhibit of receipts and expenditures accompany this report, as reported by the Treasurer.

The editorial management of THE JOURNAL has continued as heretofore under the direction of the Board, no editor having been appointed, the resident member of the Board acting in the capacity of supervising editor, and employing such editorial writers as in his judgment the occasion required.

The Association having practically passed upon the question of location, it is still the opinion of the Board that a suitable building for THE JOURNAL Office should be secured as soon as there are sufficient funds available for that purpose.

In conclusion your Board respectfully submit that they have done their best to publish as good a Journal as the funds would permit, and they have pleasure in stating that the available resources of THE JOURNAL are now such that their intention is for the next and succeeding years, to raise the professional and literary standard of its editorial department to the equal of any.

JOHN B. HAMILTON, P. O. HOOPER,
Secretary, President.

On motion it was received and adopted.

Dr. W. H. Wathen, Chairman, read the report of the Committee on Nominations:

The Nominating Committee begs to make the following report:

For President, Dr. H. O. Marcy, of Boston, Mass.; First Vice-President, Dr. Willis P. King, of Missouri; Second Vice-President, Dr. Henry Palmer, of Wisconsin; Third Vice-President, Dr. W. E. B. Davis, of Alabama; Fourth Vice President, Dr. W. E. Taylor, of California; Treasurer, Dr. Richard J. Duglison, of Pennsylvania; Secretary, Dr. W. B. Atkinson, of Pennsylvania; Librarian, Dr. Geo. W. Webster, of Illinois; Trustees, Dr. W. W. Dawson, of Ohio, Dr. W. W. Potter, of New York, Dr. J. H. Rauch, of Illinois.

Judicial Council—Dr. H. O. Walker, of Michigan, to fill vacancy; Dr. W. T. Bishop, of Pa.; Dr. G. L. Porter, of Conn.; Dr. Jas. F. Hibbard, of Ind.; Dr. C. H. Hughes, of Mo.; Dr. Hunter McGuire, of Va.; Dr. A. M. Owen, of Ind.; Dr. H. D. Didama, of New York.

Place of meeting 1892—Detroit, Mich.; time of meeting first Tuesday in June.

Chairman of Committee of Arrangements, Dr. H. O. Walker, Detroit, Mich.; Address on Gen-

eral Medicine, Dr. J. S. Cain, of Tennessee; Address on General Surgery, Dr. John B. Hamilton, of Washington, D. C.; Address on State Medicine, Dr. C. A. Lindsley, of Conn.

Committee on State Medicine—J. Cochran, Ala.; T. E. Murrell, Ark.; Luke Robertson, Cal.; T. H. Crothers, Conn.; J. R. Logan, N. Dak.; R. G. Ellegood, Del.; S. S. Adams, D. C.; R. J. Nunn, Ga.; J. P. Wall, Fla.; Harold N. Moyer, Ill.; J. F. Hibbard, Ind.; H. Wright, Iowa; W. L. Schenck, Kans.; H. Horace Grant, Ky.; C. B. Belt, Mass.; A. J. Stone, Minn.; W. F. Breakey, Mich.; W. Johnson, Miss.; Young H. Bond, Mo.; Thos. Wood, N. C.; Alfred F. Carroll, N. Y.; G. P. Conn, N. H.; Goldberth, Neb.; R. Harvey Reed, O.; L. F. Flick, Pa.; A. A. Moore, S. C.; J. P. Walker, Tenn.; R. M. Swaringen, Tex.; J. H. Hamilton, Vt.; R. N. Martin, Va.; A. F. Stifel, W. Va.; Geo. M. Steele, Wis.; J. R. Matos, La.; G. S. Beardsley, U. S. A.; W. Wyman, U. S. Marine-Hospital Service.

Committee on Necrology—J. T. Searcy, Ala.; G. W. Huds, Ark.; W. K. Lindley, Cal.; G. R. Shepperd, Conn.; L. P. Bush, Del.; J. M. Toner, D. C.; J. D. Fernandez, Fla.; G. W. Bailey, Ga.; E. P. Cook, Ill.; J. L. Thompson, Ind.; Brown, Iowa; W. F. Sawhill, Kan.; John G. Brooks, Ky.; Asa S. Potter, Mass.; R. C. Levensaler, Me.; A. B. Anker, Minn.; W. B. Alvord, Mich.; B. F. Kettel, Miss.; J. D. Griffith, Mo.; W. M. Knapp, Neb.; H. Capehart, N. Dak.; N. Jacobsen, N. Y.; J. J. Berry, N. H.; S. S. Thorne, Ohio; Jacob Price, Pa.; F. P. Porcher, S. C.; F. M. Sim, Tenn.; W. H. Wilks, Tex.; Edw. R. Camden, Vt.; L. E. Harvey, Va.; Dr. Wilson, W. Va.; H. V. Faville, Wis.; Jas. M. Flint, U. S. N.

Committee of Pan American Medical Congress—R. F. Saunders, Ala.; Ed. Bentley, Ark.; W. R. Cluness, Cal.; C. A. Lindsley, Conn.; E. M. Darrow, N. Dak.; C. H. Richards, Del.; D. W. Prentiss, D. C.; C. R. Oglesby, Fla.; James McFadden Gaston, Ga.; N. S. Davis, Ill.; A. M. Owen, Ind.; H. B. Crowley, Ia.; J. P. Minney, Kan.; J. N. McCormack, Ky.; S. T. Chaillé, La.; Augustus P. Clarke, Mass.; P. H. Millard, Minn.; C. H. Leonard, Mich.; Dr. Kendall, Miss.; I. N. Love, Mo.; Jno. Cronyn, N. Y.; Irvin A. Watson, N. H.; R. C. Moore, Neb.; Chas. A. L. Reed, Ohio; Wm. Pepper, Pa.; R. A. Kinloch, S. C.; J. R. Buist, Tenn.; J. S. Carhart, Tex.; Henry W. Holton, Vt.; J. S. Wellford, Va.; Jas. H. Brownfield, W. Va.; Jas. P. Reed, Wis.

GEORGE W. WEBSTER,
WM. H. WATHEN, Secretary.

Chairman.

The announcement having been made that Dr. S. C. Wood, of N. Y., nominated for Judicial Council, was dead, on motion the name of Dr. H. D. Didama, of N. Y., was substituted.

Dr. H. O. Walker, of Mich., moved to strike

out Hot Springs, Ark., as the place of meeting and insert Detroit, Mich.

After some discussion, Dr. Simmons, of Cal., moved to insert San Francisco, Cal. On motion of Dr. Caren, Ill., this was laid on the table.

Dr. Pawling, Neb., moved to insert Omaha, Neb. This was laid on the table.

A motion of Dr. J. M. Keller, Ark., to recommend the whole report was laid on the table.

Detroit, Mich., was then adopted as the place of meeting by a vote of 143 to 105.

Dr. C. W. Brown having named Dr. W. W. Potter, N. Y., as ineligible for Trustee by reason of non-affiliation with the Association, by the suggestion of Dr. N. S. Davis, Ill., the matter was referred to the Judicial Council.

The whole report on nominations as amended was then adopted by a large vote in favor.

Dr. X. C. Scott, Ohio, named Dr. H. O. Walker, of Mich., as Chairman of the Committee of Arrangements, in place of Dr. J. M. Keller, of Ark. Another nominee having been named as ineligible, Dr. I. N. Love, Mo., demanded the objection.

A motion by Dr. F. Woodbury, Pa., to refer this also to the Judicial Council was negatived.

The place of meeting requiring it, on motion of Dr. N. S. Davis the time was changed from first Tuesday in May to June.

Dr. J. M. Mathews, Kentucky, read the *Address in Surgery*. (See page 654.)

Dr. W. F. Horner, U. S. A., Va., offered the following which was adopted:

WHEREAS, The Code of Ethics of this Association declares, Art. II, "The benefits occurring to the public directly and indirectly from the active and unwearied beneficence of the profession," but—since its original organization has never considered any provision for the widows and orphans of deceased Fellows.

WHEREAS, The success in the formation of Medical Aid Associations in our large cities and in one or more of the States of our Union has proved a practical scheme to succor the families of many a brother physician, stricken down in the midst of apparent success, who otherwise would be unprovided for.

Therefore, be it resolved, That a Committee be appointed by the President of this Association to consider and report upon the expediency and practical advantages of a "Section of Benevolence" in connection with the work and aims of the Association, which seeks to ameliorate not only human suffering and to cure disease, but to enlarge the influence of the profession by showing regard for the needs of the widows and orphans of our deceased brethren.

The Permanent Secretary read the report of the Committee on a Secretary of Public Health.

REPORT OF THE COMMITTEE ON THE QUESTION OF A CABINET APPOINTMENT OF A SECRETARY OF PUBLIC HEALTH.

The committee appointed to consider the question of petitioning the next Congress on the creation of a Medical Secretary of Public Health, beg leave to present their views, and a resolution, for your adoption.

The under-signed believe that the time has come when the medical profession is under solemn obligation to seek all the places and positions in the State that will promote a higher degree of public usefulness than we now enjoy. There is no other profession that excels ours in positive efficiency to sustain public order, comfort and virtue. We possess vast capacity for the direction of society and promotion of human happiness. There is nothing in the body or mind of man that is not in the purview of medical practice. We are laboring unceasingly to assuage the ills of individuals and communities.

At this time the profession is manifesting, in a higher spirit than ever before, the purpose of suppressing contagious and infectious diseases. This work was begun by Jenner a century ago, and the awful scourge of small pox has been stamped out wherever vaccination is compulsory. We have now assumed the stupendous task of suppressing all the terrible diseases that desolate the world.

There are infectious and epidemic diseases that move about the world almost periodically, which we need not particularize; they are often the products of the squalor and wretchedness of peoples, and are spread far and wide about the lines of commerce. These invisible foes infest the air, the waters, and the very food we eat. From the grosser foes of human health, cold, heat and tempest, men have power to defend themselves; but in regard to these invisible agents of suffering and death, for want of higher knowledge, they are largely helpless. In their despair they turn to medical science for help, unwilling to trust in the brute law of the survival of the fittest.

Governments, in a certain way, have always done something to aid medical men in their endeavors to stay the pestilence and save the afflicted; but never adequately. They have generally refused to make the medical profession a permanent integral part in the administration of the State; that is, in the making and the execution of sanitary laws.

What laws are necessary for the full employment of our beneficent profession? We reply: those that relate to the social state of the people for the prevention of disease. They comprehend an amplitude and purity of water supply, proper dwellings for the lower classes without overcrowding or deficiency of light and air, unadulterated food, complete drainage and disinfection of excrement, the preservation of rivers and smaller streams of water from pollution, the regulation of the hours of labor, the protection of childhood from the imposition of toil, and their proper education, cleanliness of streets and planting of shade trees for protection from intense solar heat, and the decomposing power, by their leaves, of deleterious gases and miasms; the establishment of

public baths, the operations of quarantine to prevent invasion of pestilence and landing of immigrants with diseases dangerous to others, the isolation of persons attacked with infectious disease and the disinfection of localities, the construction and management of general and special hospitals, the care of the sick poor in their homes, the prevention of consanguineous marriages and of those who have destructive types of constitution, the warning of society of the evil consequences of abuses of the brain, the material basis of consciousness, whereby a free will is impaired and the sufferers become irresponsible and are often mentally ruined; and, lastly, the regulation of those two giant evils of civilization, intemperance and prostitution.

We affirm that all the measures for public relief on these important subjects should be under the guidance of medical men.

It is not the mere knowledge of the human frame as a diseased thing, or a mechanism, that should give us highest consideration in the State, but rather our capacity to prevent sickness by securing the proper administration of the laws of health. At present we occupy positions but little better than mere advisers to authoritative bodies; our soundest suggestions are at the mercy of ignorance and prejudice of uninformed legislation. The medical profession holds itself ready not only to diminish the fearful destruction of life now going on, but ultimately to destroy the contagia that cause it. It is now becoming generally known that infectious diseases and toxic elements are disseminated in food. An infectious disease in the family of a dairy-man may be as widely diffused as his distribution of milk. The pollution of streams of water and wells about towns, villages and farmers' homes, we know definitely, subject many families to tedious and destructive diseases, which our wise sanitation can overcome, if we possessed the power to so act. It will be well for the State when the medical profession is represented in the councils of the Nation as weightily as can be assumed by official places and conferred dignities.

It seems to your committee that this is a propitious period for entering upon a forward movement that will place our profession in its true relation to public affairs; and that the first and most important step to obtain this end, is to appeal to Congress to create the office of a Medical Secretary of Public Health.

The latest addition to the Cabinet of the President is that of Secretary of Agriculture, and already a great impulse to higher intelligence has been inaugurated by the practical farmer who is at its head.

What part will a Secretary of Public Health play, when he takes his place in the Cabinet? Will he be a mere figure head, or will he be able to fulfil important duties to the State? The an-

swer is, he will, by virtue of his position, justly form an integral part of the councils of the State; he will represent the medical consciousness of the Nation, and be one to whom we all can look for the exploitation of measures that will direct continuous scientific and collective investigation, in regard to endemic as well as epidemic diseases that afflict the people; he will be able to coöperate, coördinate, unify and utilize, in the discharge of his duty, all the work of State Boards of Health, now so well organized in various States of the Nation; and these in turn will find themselves strongly reinforced by the example and authority of a great central officer who will be equal in function and opportunity with the other members of the President's Cabinet.

It must be acknowledged that the Government, through the operations of the Surgeon-General of the Army, Navy, and Marine Department, and by the action of the Secretary of State, has authorized most liberal expenditures for the establishment of the National Medical Library and Museum, the issue of the incomparable Index Medicus, and for original researches at home and abroad on the origin and nature of the fearful epidemic brought to our shores by immigrant and other ships. Honorable mention is due to Surgeon George M. Sternberg, of the U. S. Army, for his investigations in regard to yellow fever, and to Dr. E. O. Shakespeare, of Philadelphia, for his study in India and Spain of Asiatic cholera under the patronage of Secretary Bayard; of the establishment of scientific posts by the Surgeon-General of the Marine-Hospital Service at Dry Tortugas for the special and continuous investigation of the causes of yellow fever, and the Bacteriological Laboratory attached to U. S. Marine-Hospitals at New York, and to the Surgeon-General of the Navy for the Navy Museum of Hygiene, in whose laboratories chemical analyses of water and food, as well as bacteriological research, are constantly going on.

The more recent enactment of the Inter-State Quarantine Act as, truly, says Dr. Walter Wyman, of the Marine-Hospital Service in Washington, marks an epoch in the history of national health legislation. The Conventions in the quarantine service, in the last few years have secured great progress towards a uniformity in quarantine laws in time of epidemic visitation. Also an extensive correspondence has been established by the Marine-Hospital Surgeon with our Consuls every where, so that our quarantine service is constantly advised of the prevalence of epidemics in countries with which we are closely connected in a commercial way.

A Secretary of Public Health, by the aid of associated departments, can be constantly informed of the prevalence of epidemic disease in all the localities of our country, and could give public warning to all who might be exposed to

them, and thus the people will be assured that a competent Minister of State surveys the whole field. He will also be able to render important assistance to Army, Naval and Marine Surgeons, by the fact that their respective Cabinet officials cannot be in professional touch with them, as would be a Secretary of Public Health.

We can all recall what this Association accomplished for the elevation in rank and pay of the Army and Naval Surgeons from the lower plane on which they stood. It was not through the active support of the President or his Cabinet; but it was only due to the appeal of this Association directly to Congress. This same effort is now being made through the British Medical Association to obtain higher rank to the medical arm of the Army and with fair hopes of success.

The question of higher medical education must also occupy a Secretary of Public Health. We all know the great progress on this line that has been made in the last twenty years. A more thorough preliminary education is now demanded by our best medical schools for matriculation; moreover, diplomas no longer give in some States a right to practice medicine. We need uniform laws on this subject in all the States, and such legislation can be greatly promoted by a Cabinet officer. If it be possible to compass this there should be a universal law that no man or woman or special sect of physicians, regular or irregular, and no specialist shall lawfully practice medicine or surgery until they have given satisfactory proof before a Board of Examiners that they have had an adequate training in medicine and surgery. In this way it is reasonable to expect that at length a race of Physicians will be developed who will secure universal respect because they will be regarded as amongst the best educated persons in a community.

The only true way of suppressing quackery among regular or irregular practitioners is by higher education. Thus the medical profession has gradually unfolded itself in the procession of the ages, and will continue to grow stronger and brighter with the progress of civilization.

It is perfectly plain that a Medical Secretary of State will be as fully employed as any other officer of the State, and his duties will increase all the time. It is a well-known biological law, that organs grow to conditions of capacity as they are continuously exercised. The muscular system and all the organs thus increase up to a condition of status; so will the functions of the proposed officer grow broader and stronger in adaptability to the needs of the people and the greater efficiency of our profession, also to this Association, which, whatever it may have achieved, is still upon the threshold of its beneficent mission to our country.

His annual reports will command universal at-

tention, as they will contain everything of importance in medical progress.

Finally, the unification of all things relating to public hygiene in the States through the aid of State Boards of Public Health, will give a solidity and usefulness to the practice of medicine never hitherto attained.

We ask for the adoption of the following resolution:

Resolved, That the President of this Association appoint a committee of five to memorialize Congress, at its next session, on the subject of creating a Cabinet officer to be known as the Medical Secretary of Public Health.

All of which is respectfully submitted.

C. G. COMEGYS, Ohio.

T. G. RICHARDSON, Louisiana.

N. S. DAVIS, Illinois.

On motion of Dr. J. F. Hibberd, Indiana, the report was received and the resolution was adopted.

Committee—Drs. C. G. Comegys, Ohio; J. C. Culbertson, Ohio; W. T. Briggs, Tennessee; J. F. Hibberd, Indiana; and Wm. B. Atkinson, Pennsylvania.

Dr. I. N. Quimby, New Jersey, offered the following amendment:

WHEREAS, More time is needed in the various Sections to enable the same to get through with their generally *overburdened* duties; and whereas one of the morning sessions, say *Thursday*, could be omitted without any detriment to the general good of the Association, I hereby offer the following amendment to the by-laws: That *Thursday morning's* general session be *omitted* and the time be devoted to moving Sectional work.

Laid over under the rules till next year.

Dr. Quimby offered the following, which was adopted:

WHEREAS, About \$1,500 or \$2,000 has been contributed towards the Rush Monument Fund, which amount is on deposit without interest, therefore be it

Resolved, That this Association direct its Chairman, Secretary, and Treasurer of said fund to be constituted a committee of investment, who are hereby empowered and directed to invest said sum at interest in *good first mortgage, real estate security, or other first class securities*.

VOTE OF THANKS TO THE EDITOR AND BUSINESS MANAGER.

Dr. R. Harvey Reed, Ohio, offered the following:

WHEREAS, THE JOURNAL has been successfully and satisfactorily conducted during the past financial year, enabling the Treasurer of the Association to report the largest balance in the history of the Association, of over \$5,000, being an increase of nearly 100 per cent. over the preceding year; and

WHEREAS, This success has been largely due to the united and energetic efforts of our Editorial and Business representatives at Chicago; be it therefore

Resolved, That the thanks of this Association be, and are hereby given Dr. John H. Hollister, the Supervising Editor, and Mr. J. Harrison White, the Business Manager; and be it further

Resolved, That this Association cordially recommend to its Board of Trustees the retention of the services of these gentlemen for the present year.

A motion by Dr. Kendall, Illinois, to lay this on the table was negatived.

After much discussion, on motion of Dr. H. D. Holton, Vermont, it was agreed that nothing in this action should be construed as mandatory upon the Board of Trustees.

Dr. Pancoast, of Pennsylvania, made the point of order, with all respect to the President and every faith in the honor of the delegates to the Association, that from a parliamentary standpoint, the President and the Association cannot tell whether the vote just passed was a legal one according to our By-laws, as the roll of delegates was not called.

President Briggs replied, that the decision of the chair could be appealed from.

Dr. Pancoast declined to do so, saying that he did not wish to consume time, and as the Permanent Members are not allowed to vote, he would not appeal to a meeting composed only of delegates.

Dr. J. S. Marshall, Chairman, read the
REPORT OF THE COMMITTEE ON CONFERENCE
OF SECTIONS.

Your Committee of Conference of Sections appointed in consonance with the resolution of Dr. Connor, passed by the Association on Tuesday morning, beg leave to report as follows: That owing to the limited time at their disposal, and the greatness of the task imposed upon them, they have been unable to perfect a plan for the improvement of the scientific work of the Sections and the strengthening of the weak ones, that seemed at all satisfactory to your Committee. As a beginning, however, in this direction, your Committee recommend the passage of the following resolutions:

Resolved, That a committee of five be appointed by each Section to supervise and revise papers submitted to the Sections, and to perform such other duties as may be directed by the Section; of this Committee the Chairman and Secretary of the Section shall be *ex officio* members.

Resolved, That the Committee of Conference of Sections ask to be continued, that the work already begun may be further perfected.

On motion, the report was received and the resolutions were adopted.

Dr. J. G. Kiernan and Dr. H. St. Clair Ash, Pennsylvania, offered the following amendment to the By-laws:

Resolved, That the Committee of Necrology be abolished, and the work of that committee be made the duty of the editor of THE JOURNAL.

Dr. W. W. Parker, Virginia, offered the following:

Resolved, That the next meeting of this Association consider the propriety of electing a practical chemist of well-known skill and high character, who shall as soon as may be begin the analysis of the various nostrums now on the market and that may hereafter appear, and publish the result in THE JOURNAL of the Association, or in an independent journal under the name of *The Moral Detective*, or *Medical Examiner*, or such other title as the Association may select, and for his compensation a tax of fifty cents per annum shall be assessed upon each member of

this Association. The chemist so elected shall have the privilege of issuing the journal to other persons, not members of this Association, upon such terms as he may think proper.

On motion this was laid on the table.

On motion the Association then adjourned.

(To be concluded.)

MISCELLANY.

A WORD TO ACRISTS.—An invitation is given to all aural surgeons to send a brief statement of their views and experience concerning the operation for excision of the drum head or ossicles. A prompt contribution to this consensus of opinion, for early publication, will be appreciated. Address S. S. Bishop, 70 State St., Chicago.

Other journals are invited to insert this notice.

THE BRITISH GYNECOLOGICAL SOCIETY.—The meeting of this Society will be held at Newcastle-on-Tyne on June 18 and 19, under the presidency of Dr. Robert Barnes. The meetings, which will be held in the College of Medicine, will be open to all registered medical practitioners. A public dinner will be held on the evening of the first day. All communications should be addressed to the General Local Secretary, R. C. Bennington, M.B., 59 Osborne Road, Newcastle-on-Tyne.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from May 2, 1891, to May 8, 1891.

First Lieut. Julian M. Cabell, Asst. Surgeon, is relieved from duty at Ft. Niobrara, Neb., for duty in person to the commanding officer, Ft. Buford, N. Dak., for duty at that post, relieving Major Valery Havard, Surgeon. Major Havard, on being relieved by Lieut. Cabell, will report in person to the commanding officer, Ft. D. A. Russell, Wyo., for duty at that post. Par. 14, S. O. 102, A. G. O., May 5, 1891.

Capt. Guy L. Edie, Asst. Surgeon, is relieved from duty at Ft. Douglas, Utah, and will report in person to the commanding officer, Ft. Niobrara, Neb., for duty at that post, relieving Major Wilcox, Surgeon. Major Wilcox, on being relieved by Capt. Edie, will report in person to the commanding officer, Ft. Huachuca, Ariz., for duty at that post. Par. 14, S. O. 102, A. G. O., May 5, 1891.

Capt. William P. Kendall, Asst. Surgeon, is relieved from duty at Ft. D. A. Russell, Wyo., and will report in person to the commanding officer, Ft. Douglas, Utah, for duty at that post. Par. 14, S. O. 102, A. G. O., May 5, 1891.

Capt. Walter D. McCaw, Asst. Surgeon, is relieved from duty at Ft. McPherson, Ga., and will report in person to the commanding officer, Camp Pilot Butte, Wyo., for duty at that post, relieving Capt. George E. Bushnell, Asst. Surgeon. Capt. Bushnell, on being relieved by Capt. McCaw, will report in person to the commanding officer, Ft. McKinney, Wyo., for duty at that post. Par. 14, S. O. 102, A. G. O., May 5, 1891.

First Lieut. Joseph T. Clarke, Asst. Surgeon, is relieved from duty at Ft. Riley, Kan., and will report in person to the commanding officer, Camp Poplar River, Ark., for duty at that station, relieving First Lieut. Jefferson D. Poindexter, Asst. Surgeon. First Lieut. Poindexter, on being relieved by Lieut. Clarke, will report in person to the commanding officer, Ft. Niobrara, Neb., for duty at that post. Par. 14, S. O. 102, A. G. O., May 5, 1891.

Capt. Louis A. La Garde, Asst. Surgeon, is relieved from duty at Ft. Assiniboine, Mont., and will report in person to the commanding officer, Ft. McHenry, Md., for duty at that post, relieving Major Charles B. Byrne, Surgeon. Major Byrne, on being relieved by Capt. La Garde, will report in person to the commanding officer, Ft. Assiniboine, Mont., for duty at that post. Par. 14, S. O. 102, A. G. O., May 5, 1891.

Major Joseph B. Girard, Surgeon, is relieved from duty at Alcatraz Island, Cal., and will report in person to the commanding officer, Benicia Bks., Cal., for duty as Post Surgeon at that post, and Attending Surgeon at Benicia Arsenal, Cal., relieving Major John H. Janeway, Surgeon. Major Janeway, on being relieved by Major Girard, will report to Philadelphia, Pa., and assume the duties of attending surgeon and examiner of recruits in that city, and in addition to his duties in Philadelphia, will perform the duties of Post Surgeon at Frankfort Arsenal, Pa. Par. 14, S. O. 102, A. G. O., May 5, 1891.

By direction of the Acting Secretary of War, par. 5, S. O. 24, January 20, 1891, from this office, granting Major Julius H. Patolzi, surgeon, six months' leave of absence, is so amended as to grant said leave on surgeon's certificate of disability. Par. 15, S. O. 99, A. G. O., May 1, 1891.

ADDRESSES.

THE ADDRESS ON MEDICINE.

Delivered at the Forty-second Annual Meeting of the American Medical Association, held at Washington, D. C., May, 1891.

BY E. L. SHURLY, M.D.,
OF DETROIT, MICH.

Mr. President and Members:—As it would be improper on this occasion to attempt even a mention of the vast number of interesting and instructive ideas and observations connected with the science and practice of medicine, which has been evolved during the past year, I shall present for your attention only some points bearing on

THE RELATION OF MICROORGANISMS AND TOXINES TO THE SO-CALLED ZYMOTIC OR INFECTIOUS DISEASES,

and as this subject in its various ramifications is too vast for a detailed consideration, I must of necessity confine myself, in great measure, to a generalization upon the biological and chemical features involved. While laboratory work has done perhaps more than any other branch of science toward clearing up many vexed questions about physiological and pathological activities, yet to be of lasting value and guidance it must agree with general and clinical observations. While this has been the case more often than otherwise, yet there are instances where laboratory observations and clinical data have crossed swords!

Before proceeding to an examination of the topics mentioned, it will be necessary for us to keep in mind the fact, that the organized animal body is composed of, and is under, the operation (the same as other bodies) of the three elements of the Universe, Ether, Energy and Matter, under various forms and methods of combination; to which may be added what is known as "Vital Force," which some scientists regard as "energy of position" from the combustion of food. Also that this fact applies to a condition of *disease* as well as health! For in Somatic death, even, *i. e.*, death of the whole body, there are certain elemental tissues which die first, such as the blood and parenchymatous tissue, while certain other tissues, such as the epithelial, resist for a time, at least, the destructive or resolving power of Kinetic

Chemical energy. In fact, the only difference between life and death from a physical point of view, consists of changes in the molecular or atomic arrangements under the direction of chemical, calorific, or electric energies. For *matter* and *energy* are indestructible! As Shelley says, "I change, but I cannot die."

To understand at all, the range of pathology and pathological chemistry,—to which we must undoubtedly look for the solution of many of the problems of the present day, it will be proper to take a brief survey of physiology and animal chemistry, which may be considered the foundation stones of our art.

To sum them up according to Mills, Foster and Kirk, we have

The Proximate Principles, which are:

Nitrogenous—Proteids.		
Organic	Non-nitrogenous	{ Certain Crystalline bodies. Sugars (Carbo-hydrates). Fats (Hydro-carbons).
The Inorganic	{ Mineral salts. Water.	

The proteids are the chief constituents of living tissues, including the blood and lymph.

The molecule is highly complex, consisting of a great number of atoms, and is formed of the elements C, H, N, O, S. and P., although some chemists think that we are still in ignorance of its exact molecular constitution. The proteids are amorphous and non-diffusible, excepting the peptones. They are soluble in strong acids and alkalies with change of properties and constitution. In general, they are coagulated by alcohol, ether and heat. They may be classified into:

Native Albumins: Egg-albumin, serum-albumin.

Derived Albumins (albuminates): Acid-albumin, alkali-albumin, including syntonin (from muscle), para-peptone, and casein.

Globulins: Globulin, paraglobulin, fibrinogen, myosin, vitellin, globin.

Fibrin: Coagulated proteids.

Peptones: By the decomposition of proteids (albumin) by digestion with pepsin we obtain: Antialbumose, anti-peptone; and with trypsin, hemi-albumose, hemi-peptone, leucin and tyrosin.

By decomposition with acids, we get with hydrochloric acid: antialbumate, antialbumid, hemi-albumose and hemipeptone.

And with *sulphuric acid* we get antialbumid, hemialbumose, hemipeptone, leucin and tyrosin, and lardacein (an amyloid substance).

The nitrogenous, non-crystalline bodies allied to proteids are: mucin, chondrin, gelatin (or gluten), elastin, keratin, nuclein, chitin.

Carbo-hydrates (Sugars): Dextrose, maltose, lactose, inosit, dextrin, glycogen, tunicin.

Fats, Fatty Acids, etc.: Formic acid, propionic acid, acetic acid, butyric acid, valerianic acid, caproic acid, capric acid, caprylic acid, laurostearic acid, myristic acid, palmitic acid, stearic acid.

The Oleic (Acrylic) Acid Series: Oleic acid.

The Neutral Fats: Glycerin.

The Glycolic Acid Series: Glycol.

The Lactic Acids:

Bibasic Acids (Oxalic Acid Series): Oxalic acid, succinic acid.

The complex nitrogenous fats (which are obtained from nerve tissues) such as lecithin, glycerin, phosphoric acid, protagan, neurin, cerebrin.

The Series of Bile Acids, etc.: Cholic (or cholic) acid, glycocholic acid, taurocholic acid, and cholesterin; which has been said to be the only free alcohol formed in the body.

The Bile Pigments: Bilirubin, biliverdin, choleletelin, hydrobilirubin.

The Pigments of Urine: Urobilin, uroerythrin.

The Indigo Series: Indican, indigo, indol, skatol.

The Nitrogenous Metabolites: Urea, urea nitrate, uric acid, creatin, creatinin, allantoin, hypoxanthin (sarkine), xanthin, carmin, guanin, kynurenic acid, glycine, taurin, leucin, asparagin, amido succinamic acid, aspartic acid, glutaminic acid and cystin (an amido-acid).

The Acids of the Benzene, or Aromatic Series: Benzoic acid, hippuric acid, phenol, tyrosin.

In addition, we must include the leucomaines, for the discovery of which we are chiefly indebted to Gautier.

According to Vaughn and Novy there are three groups, which they classify as follows:

The uric acid group, in which they enumerate ten bases. The creatinin group, consisting of seven bases, and a third, undetermined group.

Besides these Brieger, Gautier, Hoppe Seyler and others, have isolated from animal and vegetable organisms in various states of decomposition, about forty substances called ptomaines, some of which exist, and are formed, at times, in the human economy—especially in the intestinal canal. Now, when we contemplate this vast array of physiological and pathological chemical products of the laboratory of the animal body, some of which are so noxious if retained in certain situations or are deflected from certain courses, we ought not to be surprised at the ease with which that equilibrium of the functions—called Health—may be upset; especially as the so-called civilized human being is not only an artificial

animal with artificial impulses, and a great range of volitional power; but is assailed on every side by enemies of a parasitic nature, which, if successful in the "universal struggle," may greatly hinder the molecular and chemical coördination. Many thinkers have maintained that the biological were not distinctive from the chemical processes in Nature; but, although intimately connected, we must recognize the difference between the peculiarly vital character of molecular and blastic changes concerned in cellular movement, growth and development, such as Karyokinesis; and those changes which, from time to time, take place in the composition of the proximate principles in the nature of fermentation or oxidation, which are strictly chemical.

We know that certain irritations of a chemical, mechanical, electrical or calorific nature may be transmitted to vessels, so as to produce stasis and inflammation, or, directly to leucocytes, or other cellular elements, so as to induce other changes—degenerations—such as the albuminous, amyloid, waxy, lardaceous, caseous or hyaline. We also recognize that there are various degrees of susceptibility and resistance belonging to different tissues, and at different times under equal provocation, so that the blood, leucocytes, and other cells which under the influence of the nervous system, are the most important agents in carrying on the oxidation and nutrition of the body, may become the agents of tissue destruction. As Armory says, speaking in a general way of the nutrition and formation of healthy tissue: "We may classify these under two principal heads. That of metabolism, which comprises the whole range of transformation under the influence of chemical processes, and by means of which proteid substances undergo their many changes; and that of cell proliferation, by means of which the cells are multiplied." These metabolisms, whether of the constructive or destructive character, are chiefly performed by *functionally active cells*.

Although the question of independent trophic nerve action is still unsettled, we know that the influence of the vaso-motor system over the blood and nutrition is very great; for strong external stimuli, such as shock, etc., will produce changes of a physical character in the blood. Wertheim found that the blood of animals which had suffered severely from extensive burns showed afterwards the presence of foreign bodies—yellowish granules, besides increased fluidity, and disintegration of the red blood corpuscles.

Concerning animal chemistry there is but comparatively little known! However, we have seen from the immense variety of chemical substances already discovered to be results of fermentation, or chemical action and reaction, what the probable changes are! Laboratory experiments by Kolb, Munk, Peterson of New York, Shaw and

others show that electrical energy is capable of producing great chemical transformation and decomposition in organic substances, outside the body. They show also that similar changes, either primarily or secondarily, may be produced in living tissue. These observers have thus carried into the system such substances as iodine, strychnia and quinia, in proof of which, these substances were found in the urine in twelve hours or so afterwards. Zinseli has demonstrated beyond doubt, physiological, chemical, and caloric effects upon living tissues by electrical energy—electrical osmosis—as he called it.

Protoplasm, composed of carbon, hydrogen, oxygen, nitrogen, sulphur and phosphorus, arranged into a very complex molecule, which is "the physical basis of life," as Huxley says, and which is the main substance of all animal and vegetable cells, seems capable of the widest degree of change; by "its universal and constant waste; and its repair by interstitial formation of new matter similar to the old."

"Its power to give rise to new forms similar to the parent ones by a process of division. Its manifestations of periodic change in constitution developing decay and death."

Mills, Foster and other physiologists state that protoplasm is not a single proteid substance, but a mixture of such. It contains often also starch, fat, chlorophyl, etc. The *cell* is composed of protoplasm, nuclein, plasmin and chromatin as Dr. McCallum, of Toronto (who has been investigating nutrition), calls the coloring matter of animal cells. Protoplasm under nerve influence constructs a certain substance which is antecedent to another final product, which is called a ferment. According to Vonjaksch, when fibrin or other proteids are acted upon by pepsin and hydrochloric acid at a proper temperature, etc., the proteid passes through several stages before being finally converted into peptone.

The proteid molecule seems to be split up and the albumoses are the first bodies formed. Kuhne describes a proto-albumose, hetero-albumose, and deuto-albumose. Passing to the blood, which is such an important tissue both in health and disease, and so involved in any consideration of protoplasm, we find its chemical composition to be water, proteids, salines, fats, and extractives. The proteids being known as para-globulin, globulin, serum-albumin and fibrinogen; the principal extractives: urea, creatin, and allied bodies, sugar and lactic acid—the serum containing the alkaline salts. The different corpuscles make up from one-third to one-half the weight of the blood, and of this, the red corpuscles may be said to constitute a greater part. The colorless cells are known to contain, besides protoplasm, peculiar granules, fats, glycogen, lecithin, protagon, and other extractives. One especial interest attaches to the red corpuscles, on account of

their containing, organically or intimately combined, iron.

There have been very many interesting studies in relation to the blood and nutrition, of late, which we have not the time to notice. Physiologists have, however, found different actions of globulins, para-globulins and fibrinogen in serum. The behavior of coagulation, and the action of so-called fibrin fermentation is not without interest from a pathological point of view, for we shall probably find, in the future, that in many of the general diseases, characterized by parenchymatous inflammation, such as lobar pneumonia, the disease may be due to this vital process—including chemical changes of local origin and influence; for it must strike every one who gives thought to it, that some of these diseases, at least, affecting organs are not essentially inflammations, but are diseases of the blood, as has been found by my colleague, Dr. Gibbs, in some investigations now being made upon pneumonia. What Virchow terms parenchymatous inflammation, that is, cloudy swelling or parenchymatous degeneration, met with in many febrile diseases,—especially the infectious fevers and septicemia, and after poisoning by arsenic, phosphorus or strong mineral acids is, probably, due initially to some local change in the blood and cells of the part.

Dr. W. C. Glasgow, of St. Louis, pointed out a similar pathological condition in connection with some forms of acute pulmonary diseases a few years ago.

Payne considers the granular degeneration so often accompanying febrile or inflammatory infections as a *passive* and not an *active* process, resulting from the action on the epithelium or parenchymatous elements of a part, of some injury, which, acting on the vessels and connective tissues, produces hypercemia exudation and cell-diapedesis. Another supposition is, that these molecular changes are the consequence of the high temperature to which the tissues are subjected during febrile conditions.

Concerning the typical physiological ferments contained in the saliva, gastric juice, pancreatic juice and bile, we ought to say a word. Saliva is composed of proteids, mucous and salts. Its principal function is in reducing starchy matters of food to sugar. It produces besides dextrose and maltose, acridodextrine. This takes place in an alkaline solution; but a feeble acid added will be sufficient to stop the action. The active ferment of this fluid is *ptyalin*. The activity of gastric juice is due to the ferment, *pepsin*. The exact nature of the process by which proteid is changed to peptone is not known. This proteolytic action is possessed by some vegetable organisms which are said to form a para-peptone.

Bile.—In the composition of human bile we have bile salts, soap and fats, cholesterin, lecithin

and glycocholates, and taurocholates, also waste products, such as *hemoglobin* and *cholesterin*. The digestive action of bile consists mainly of resolving mucous into a proteid and an animal gum; it also assists pancreatic fluids in the emulsifying process, and thus allows of more ready osmosis.

Pancreatic juice.—The organic constituents are alkali-albumin, peptone, leucin, tyrosin, fats and soaps, and indol. It is amylolytic, proteolytic, and steaptic. These powers are attributed to three ferments, amyllopsin, trypsin, and steapsin. Proteid digestion is carried still farther than by the gastric juice, and we have a quantity of the non-crystalline nitrogen compounds formed, leucin, one of the amido groups in the fatty acid series, and tyrosin, one of the aromatic series. Now with all this biological, chemical, molecular, and fermentative action going on in the human body, forming a great number of simple and complex organic substances, not only innocuous but poisonous, being ranked as tissue, as well as functional poisons, may we not find abundant cause for disease? Peptones injected into the blood of a healthy animal, according to Brunton, will cause death. Even the healthy blood of one species of animal injected into that of another, will cause death from non-adaptability, according to Mills.

The experiments and observations of Dr. Stockton, of Buffalo, showing the deleterious effects produced by the entrance of the Portal blood into the systemic circulation is highly instructive as bearing on this point.

Microorganisms and many enzymes injected into the blood are readily destroyed, as pointed out by Mitchell, Prudden, and others. Although there is a parasite (the *filaria sanguinis hominis*) which is known to inhabit the blood. Many observers believe that certain febrile states are caused by the absorption into the blood of peptones, which have gone through and not been split up by the liver into globulin. It is not improbable that absorption of ptomaines from the intestinal canal (which always contains some) may account for many of the so-called "malarial attacks" which so often serve as mantles of relief to our bewildered diagnostic sense. The proof of which may be assumed from the prompt relief which ensues from a brisk cathartic oftentimes. That dangerous condition known as ammoniemia and acetoniemia is more likely due to the absorption of ammoniac toxins (the result of perverse chemical action) than to the presence in the blood of a special micrococcus. However, it is argued by those who have found microbes in urine, freshly voided, in that diseased condition called bacteriuria, that the microorganisms are the essential cause. It is known to physiologists that after severe exercise the alkalinity of muscle juice is changed to acid, due to the presence of sarco-lactic acid. May we

not see here the possibility of a combination with some organic base, so as to constitute a poison, the absorption of which determines disease. The chemical examination of sputum in various diseased states of the respiratory apparatus, shows, according to Kossell, Hoppe-Seyler, Salomon, Vonjaksch, Filelue, Stonikow, and others, the presence of peptone, serum albumin, cholesterin, acetone, acetic, butyric, and caproic acids. Glycogen, and ferments resembling pancreatic ferments, besides a large number of different bacteria.

Bitter and Rietsch have shown that cholera microbes contain and elaborate a peptonizing ferment, and Hueppe has shown by experiment that the so-called cholera bacillus produces a toxine, the peculiar properties of which he has demonstrated on healthy animals.

The researches of Kossell show that among the decomposition products of nuclein are found guanine, which occurs in plants and vegetables. The tissue of some animals contain adenine, hypoxanthine and xanthine. Guanine and creatine are said by Vaughan and Novy to mutually replace one another. Creatine is considered by Hoppe-Seyler as an intermediate product in the formation of urea. The cholesterin, found in the body is capable of many chemical substitution products. An analysis of the thyroid gland by Bubnow gave hypoxanthine, paracetic acid, and a proteid substance which he named threoprotein.

Nothnagel found that the bile acids taken up into the circulation interfered with nutrition, producing fatty degeneration of organs or lymph glands. Among other poisons called by Brieger toxins, may be mentioned the so-called cadaveric alkaloids, such as neuridine, cadavarine, saprine, mydaleine, putrescine, muscarine, choline, and pepto-toxines. We obtain also, from the putrefaction of albuminous matters, formic, acetic, butyric, valerianic, palmitic, acrolic, acrotomic, glycolic, lactic, valero-lactic, oxalic, glutaminic, and aspartic acids, and various ammonias, besides numerous amine bases, such as propylamine, trimethylamine, etc., also the fixed alkaloidal bases, some of which are given above. Martin and Wollenden, by their experiments, show that the poisonous property of jequirity or abrin resides in a globulin and an albumose. They also show that peptic albumose is poisonous to dogs. They give an interesting table of comparison of these with snake poisons. Poisonous alkaloids from articles of food have been separated by Brieger and others, in some instances, and are now recognized as probable causes of disease. The question of fermentation as set up by microorganisms and the production of enzymes and toxins by them, is a leading one, and as yet unsettled. We have seen that these processes go on in nature in all instances of decomposition and putre-

fection. The chemical effects may be typically illustrated by the action of toruli and other yeast fungi, which, by fermentation, produce alcohols, acetic acid, etc., from saccharine substances. Parvinski has published the clinical history of a case of asthma in a young person in which the urine contained a large quantity of acetone during the paroxysms. A similar process of fermentation has been pointed out by Brieger, Hueppe, Vonjaksch, and others in relation to the cholera bacillus, as shown by the poisonous effects on animals, by the introduction of the toxine which they had separated from the bacillus culture, and which they believe to have been produced by the bacillus. Klebs and Loeffler have also discovered that the diphtheria bacteria produces a ptomaine which may be the cause of the general infection, the microorganism being only local in its operation, a theory advocated years ago by Oertel. Loeffler could not find the bacillus in the blood, and believes that it always resides outside the body, while the toxine is the real poison.

Brieger and C. Fraenkel have shown that diphtheria bacteria produces two poisons, one of which acts toxically, while the other secures immunity. Zueglig claims to have isolated a poisonous crystalline alkaloid from tubercle, which he believes capable of producing the disease. Herman Scholl, of Prague, confirms the conclusions of Brieger and Fraenkel that both anaerobic and aerobic bacteria produce poisons (toxines) or enzymes. The former more than the latter. Dr. F. Lydston, of Chicago, has shown that the evolution of venereal disease is not due to a coccus, but a ptomaine which inhabits the vagina, proving this by experiment. Many observers, however, claim to have found the coccus of gonorrhoea in the joints. There is much doubt as to the exact part played by the bacillus of typhoid fever, and without giving the controversy between Klebs, Eberth, Koch, Meyer, Friedlander, Gaffky, and others, it is probably as Ben-ner and Peiper say, not really pathogenic, and that the disease is produced, as Brieger suggests, by a toxine. Dr. Gibbs and myself found that sterilized watery extract of tubercle would kill a newly hatched white-fish in fifty-five seconds, completely permeating the protoplasmic mass, while an alkaline extract would do so in about sixty-five seconds. Mice afterwards injected with the fish show no signs of septicemia or other disease, but die if injected with the same extract. Thus showing a peculiar affinity between protoplasm and tubercle toxines.

To discuss in a special manner the saprophytic and pathogenic bacteria concerned in a full biological study would take so much time that I can only, as it were, allude to them.

In Eisenberg's tables of known bacteria for laboratory use one hundred and sixteen species are enumerated, etc.

We have found that when guinea pigs were injected subcutaneously with the extracts made from the lundings of monkeys dead of their ordinary phthisis pulmonalis (which is characterized by marked emphysema, the only life is more fever with catarrhal symptoms lasting about two weeks. On the other hand, when injected with an extract made from tuberculous lungs from the human being, general tuberculosis followed. The morbid anatomy of the monkey lung is identical from an ordinary view, with that of human phthisis pulmonalis. This probably illustrates the condition which all pathologists recognize now as *pseudo-tuberculosis*. I am aware that it is generally accepted that bacteria or their spores are the essential cause of most, if not all of the infective diseases. And the results of bacteriological investigation during the last few years would seem to support such a doctrine, for the following reasons, viz.: That they can be isolated by color reaction and thus directly connected with the diseased body where found. Moreover, they require a certain time for development, thus corresponding to the period of incubation of such diseases; many of them being ectogenic and saprogenic, anaerobic, or aerobic, can thus live until the opportunity for invasion offers. Being endowed with *life* and multiplying enormously, they can strenuously resist destruction. Being protoplasmic (composed of albuminous material and microscopic they can more readily affiliate with animal fluids, cells and tissues. Existing in a passive or quiescent state as well as an active one, they can behave like vegetable seeds and spores, and preserve a long period of latency. For these, as well as other reasons which could be adduced, we are led to believe that bacteria must be the cause in some way or other of the zymotic or infectious diseases.

But the question arises, how do they accomplish this? By mere local growth for a parasitic life, by a secretion of material from themselves, in other words, are they secreting cells? or, by inducing at once chemical changes or fermentation of a destructive character with the formation of new substances—poisons?

If we examine carefully into the basis on which certain forms of organisms stand as the materies morbi of a given disease, we shall find that those who are so strong in their faith in the essential microbic origin of disease have not in some instances looked fairly into the status of affairs. For instance, take the case of the comma bacillus of Koch, Fraenkel, in his text-book of bacteriology, third edition, says: No case of genuine cholera has as yet been reported in which the comma bacillus has been absent. From the context, he probably means in the intestines. This has been undoubtedly disproved! This illustrates again what was said at the outset, that all of these questions should be looked at without

bias as far as possible, without regard to nationality, and from the stand-point of clinical as well as laboratory experience.

In whatever manner their life history is exemplified certain effects have been observed connected with them, as a class. Their career *ad interim* from one animal to another is not well known (excepting perhaps the bacillus of anthrax). Some people supposing that they may be saprogenic at first, and thence transformed to pathogenic. In the case of many of them, their spores have either never been really demonstrated to exist, or their behavior formulated. Most species, if not all, are destroyed by the healthy fluids or tissues, and hence their destiny depends upon a favorable *nidus* or *pabulum*, which means disease. It is obvious that their artificial culture in media outside the body or in the lower animals can only approximately reflect their real natural growth and development, for in no instance is it possible to transfer the artificially cultivated microorganism to an animal with the absolute certainty that *nothing else* accompanies the bacterium. Take, for instance, tubercle bacilli, the study of which has given the most satisfactory results. We are being inoculated day by day with tubercle bacilli from the air. Why do only escape? Because some are so healthy that they are immune. But how is it that every guinea-pig inoculated gets tuberculosis? The radical believers in microbiosis say, because they are all susceptible. But the probable explanation is (like that of diphtheria), that the *materies morbi* is introduced and carried away by the lymphatics and sets up a general chemical change. There is also local change, abscess, at the situation of the inoculation from which are furnished spores which may flourish in the blood or lymph fluid afterward, where they will now find suitable pabulum for development, thus showing the fact that certain bacteria, at least, develop or act under certain conditions only, and upon a particular *nidus*. Their chemical composition is unknown during a state of activity. That certain species only appear to be pathogenic, would imply a state of specialization analogous to living nucleated cells. That their action is local, primarily, in all cases, may be assumed, because their behavior in no way shows that they themselves invade or maintain their existence in the blood or lymph fluids, because the blood would destroy them. For there are but few instances recorded of any one having found bacteria in the blood, unless we except the anthrax bacilli. Therefore it is probable that pathogenic bacteria develop only where some *previous disease* or *abnormal state* of the body suitable to them exists. That having found such, they take root, as it were, and there by catalytic action primarily, and secondarily, give rise to a particular *toxine* or poison which in turn acts selectively as a tissue poison!

The various facts stated of a *toxine* connected with diphtheria, typhoid fever, cholera, suppuration and abscess (which has been shown to be independent of bacteria), croupous pneumonia, scarlatina, phthisis pulmonalis, syphilis, tetanus, gonorrhoea, cobra and other snake poisons, etc., together with the well known (chemical) noxious products forming constantly in the body, are sufficient, it seems to me, to show that the etiological agency of bacteria are *mediate* and not *immediate*!

This catalytic action coincides with clinical observations in many directions, as, for instance, the action of snake poisons, as shown by Weir, Mitchell, and the British India Sanitary Reports. From the cobra (one of the most deadly of serpents) an alkaloid as the active principle has been separated, but how far its virulence has been tested we do not know.

There are formed in certain plants, as we know, very poisonous alkaloids and glucosides, many of them corresponding in chemical character and physical behavior to animal alkaloids and colloids; solanine, for instance, is a basic glucoside which under the influence of dilute acids splits up into solanidine and sugar. Both of these active principles are blood poisons belonging to the group of sapro-toxines.

I would say that the experiments of Dr. Gibbs and myself, point to the same thing as to the nature and behavior of tubercle when cultures or extracts are introduced subcutaneously. We have also observed that the insufflation of sun-dried sputum (tubercular) will produce phthisis pulmonalis, while the inoculation of sputum (phthisis) which has been long dry from age will not produce tuberculosis. This seems to have been confirmed by some recent experiments made by Dr. Stone in the Harvard Laboratory, who inoculated guinea pigs, with negative results, with sputum which had been long dried, and which was probably from a case of phthisis pulmonalis. We are now carrying on an investigation to ascertain the effects of inoculating guinea pigs with sputum from phthisical patients, which sputum has been dried in the sun in Southern California, under the supervision of Dr. Norman Bridge, of Chicago. The investigation has not proceeded far enough to show just what effects it will have in the production of tuberculosis, but one remarkable result has already been obtained. Six guinea pigs were inoculated, and within thirty-six hours after the operation two died of septicaemia, showing that this effect, which is a frequent result of inoculation with sputum taken directly from patients, is probably not caused by any organism, and thus coinciding perfectly with observations which Payne gives in his text-book relating to the occurrence of septicaemia without microorganisms having been discovered in connection therewith.

Concerning the tubercle bacilli, the bacilli

immediately produced in the several diseases known as tubercular, why would any previously prepared nidus be necessary? If they, or their spores (which have not as yet been satisfactorily demonstrated) are constantly invading us (which is undoubtedly true), they must at once be destroyed, or, if gaining access to the fluids of the body, would set up mechanically or otherwise, inflammation and peculiar effects as any other foreign body would. But as such microorganisms must find just the proper conditions for development or not develop, we may assume that such conditions imply previous disease, such as caseation, whether tuberculous or not. We have already seen what complex and delicate processes attend the changes of proteids, and how easy, by radical or atomic substitution, one may be changed into the other; we can therefore see how probable it is that these microorganisms operate by a peculiar property which enables them to decompose or exercise a catalytic action on certain states and kinds of proteids. The subject of immunity and susceptibility of course cannot be discussed here—suffice it to say that the ideas and experiments of Trudeau of New York, and McLaughlin of Texas, in this direction, are worthy of careful attention, and apply not only to microbes but to chemical substances connected with them. To say nothing of the chemical action and products normally evolved, as already explained, Abelous has obtained sixteen species of microbes from the empty stomach by lavage; seven of these were well known varieties, ten of these attacked and changed albumin, twelve fibrin, and nine gluten, ten caused transformations of lactose into lactic acid; thirteen formed a variable quantity of glucose from starch; rapid and energetic decomposition with evolution of gas, leucin, tyrosin, indol, skatol and ammonia compounds took place in presence of saliva. I do not know that all of these observations have been confirmed. But we have confirmed his experiments regarding albumin, which is readily transformed by saliva in the presence of microorganisms outside the body. Experiments with invertin, a ferment found in the intestinal canal, have shown some interesting results in relation to microbe metamorphosis, which are still, however, *sub judici*. Jaccoud finds the pneumococcus, besides several other forms of bacteria, in diphtheria. He believes that individual reaction is what determines the disease.

What application can be made therapeutically of the facts obtained? It is manifest that the diseases in question are caused in some way by the presence or entrance of microorganisms. Therefore the main therapeutic indication is to attack them, or neutralize their operation. We have seen that bacteria either produce for themselves or from the organic substances which they attack, a poison, or enzyme, and that this can be cultivated outside

the body in some instances. Pathological chemistry has not demonstrated with exactness the nature of all of these poisons, or classified them, but it is fair to believe that such will surely take place in the near future. Although it is generally supposed that the inorganic chemicals are not tissue poisons, but act only upon the functions through the nervous system, yet we believe that such is not the case when we observe the tissue changes produced by iodine, bromine, phosphorus, arsenic, the silver, gold, platinum and cupric salts, besides some of the vegetable alkaloids. Dr. Gibbs and myself have been able to neutralize the toxic effect of tubercle by admixture with chlorine iodine. Chloride of gold combined with glycerine, salts of platinum and glycerine and peroxide of manganese, outside the body, and with the chlorine, iodine, and gold and sodium chloride in inoculated animals. That certain chemicals have a selective action on tissues cannot be doubted; take, for example, the hypodermic injection of cantharidin used a few years ago by Cernil and Ranvier, resulting in the production of inflammation of the air passages; also the work lately of Liebreich in injecting cantharadate of potassium for the cure of phthisis pulmonalis and tuberculosis, which he believes produces exudation, as when applied to the skin. Also the selective action of strychnia and atropia, the latter acting on the secretory cells of the salivary glands, stopping secretion notwithstanding the induction of hyperemia. Arecidine, a volatile liquid alkaloid from the areca nut, has a selective action on the heart and is excreted unchanged. Harnack probably states the truth in saying that the action of drugs is molecular and fermentative. On account of the changes which remedies are apt to undergo in the stomach and intestines, by being oxidized or otherwise changed before absorption into the system, the rational way, it seems to me, is to introduce the agent hypodermically; in this way it is possible to get effects which cannot be accomplished otherwise. Dr. Launderer has obtained beneficial effects in phthisis from hypodermic injection of balsam Peru, which he says goes at once to the diseased part, thus simulating animal fluids or cultures, as exemplified by the effects of Koch's lymph and similar cultures used before by Pasteur, Grancher, Martin, Rengi, Gibbs and others. Dr. Behring has lately found that a number of chemical substances used hypodermically, such as aurochloride of sodium, naphthaline, and trichloride of iodine, were capable of neutralizing the poison of diphtheria in guinea pigs, but the most active of all was the trichloride of iodine. He also practiced, in diphtheria the plan of vaccinating the animals with bacilli cultures. Prof. Merzolski reports much better effects from bromide of gold used hypodermically (in $\frac{1}{4}$ and $\frac{1}{2}$ gr. doses), than by the usual way of administra-

tion of bromides. The prompt effects of Sammeter's treatment of erysipelas by carbolic acid injections, are well known. The superior effects of the treatment of syphilis, by hypodermic injection of cyanide and bichloride of mercury and chloride of gold and sodium are striking, as we all know. Dr. Zumbali, of Rome, found hypodermic injections of chlorodyne in profuse diarrhoea particularly superior to its administration by the mouth. The hypodermic injection of ergot for the relief of hæmoptysis is another example. This agent, administered in considerable quantity by the mouth, will often fail, whereas one, or at most two, hypodermic injections of $\frac{1}{16}$ or $\frac{1}{8}$ gr. of ergotin will generally stop a severe attack. Digitalis also acts upon the cells and vascular system more certainly when so administered. I may also mention the beneficial effects of strychnia used hypodermically, in typhoid conditions. That animal poisons can be neutralized in the body, I believe, will soon be more generally demonstrated. The experience of Tyndall, of New York, in the vaccination process for the cure of tuberculosis, promises well. Hemmeter has stopped the course of diphtheria by the vaccination of the patient with an erysipelas toxine; and Prof. Grancher states that persons suffering from tenia tonsurans are immune from diphtheria. This would seem to show that there must be a sort of antagonism or isomerism between animal and chemical poisons; and why may not more universal application be made of this principle, with a view of obtaining more specific therapeutic agents and effects? The ethereal oils, on account of their diffusible antiseptic properties, are undoubtedly applicable to the neutralization of disease when used hypodermically, and may prove yet of great value in the zymotic diseases. We are now engaged in using some of them in this way, and find that they actually provoke the liquefaction of effused products. We are also experimenting with members of the benzoin and formic acid series, and the toluidines, in an endeavor to learn their action on metabolism and disease poisons. Dr. Emil Schutz believes that drugs act topically on the secretions by precipitating albumin. He also demonstrated, by cases, that tannic acid may produce urticaria by external application alone. Galezowski, of Paris, has lately discovered a new bactericide, by the decomposition of an aniline dye, which has the same properties as pyoktania on the tissues. In this direction we may look for brilliant results, on account of the action of these substances on albuminates. My chief object is to awaken a more general interest in physiological and pathological chemistry, to the end that we may as speedily as possible acquire a scientific chemical therapy, and thus release her from the dungeon of empiricism, where she has been imprisoned with so little light these many years.

THE ADDRESS ON STATE MEDICINE.

Read at Fiftyth at the Forty-second Annual Meeting of the American Medical Association, held at Washington, D.C., May, 1894.

BY W. L. SCHENCK, M.D.,

OF TOPEKA, KANSAS, PROFESSOR OF STATE MEDICINE AND PATHOLOGY IN THE KANSAS MEDICAL COLLEGE.

Mr. President and Fellows of the American Medical Association:—While I appreciate the honor of the Address on State Medicine, I comprehend the difficulty of doing honor to a position so ably filled by Dr. Henry I. Bowditch, Dr. J. L. Cabell, Dr. George H. Robt., and other distinguished physicians and sanitarians. I am as another Ruth in the already well gleaned fields of Boaz.

If the importance of the subject assigned to me required emphasis, it could receive no stronger than was given to it at the last meeting of the Association, when its honored president, Dr. E. M. Moore, devoted much of his address to it, while the distinguished Father of the Association, Dr. N. S. Davis, in the Address on General Medicine, dwelt upon the same theme.

State Medicine, narrowly defined, is the control of disease through legislative enactments. In its broader signification it includes all that tends to the prevention of disease and to the fullness of life.

The various departments of medicine exist because health is more to be desired than disease. That department then which preserves health and prevents the development of disease is the peer of any whose function is to remove disease and restore health. Hitherto cure has been the chief thought of the scientific physician. Henceforth prevention will be his noblest theme.

While no new discoveries have been made in this important field during the past year, there has been a notable advance along the whole line, and the importance of aseptic and antiseptic conditions has been more and more pronounced.
